# Introduction

---

In 1950, the U.S. Atomic Energy Commission established the Savannah River Site with the mission (1954-1992) of the production of nuclear materials, primarily tritium and plutonium. The Savannah River Site (SRS) is a Department of Energy (DOE) facility located approximately 20 miles from Aiken, SC. Approximately 310 square miles, SRS boundaries lie within Aiken, Allendale, and Barnwell counties. During the course of normal operations, radionuclides were released into the ground, groundwater, and atmosphere. Although the reactors at SRS are no longer operating, work continues at SRS the focus being on cleaning up legacy wastes and remediation.

Due to the large number of contaminants that could be potentially released from SRS, the Centers for Disease Control and Prevention (CDC) performed a site assessment to determine the potential health effects of any released radionuclides to the off-site public. The five production reactors (R, K, P, L, and C) were the primary sources for key radiological contaminant releases. All of the radiological releases originated from processes associated with the reactor areas and the separations areas. However, there are additional areas of releases as a result of the varied processes at the SRS. Following are background descriptions of the most prevalent contaminants.

Tritium was one of the principle nuclear materials produced at SRS to multiply the firepower of plutonium in nuclear weapons (Till et al. 2001). Tritium releases originated from processes associated with the reactors, separation areas, D-Area, and tritium facilities. The two main types of tritium releases came from direct site facility releases and migration from seepage basins in the separation areas, the burial ground, and the K-Area containment basin. In the early operational years, nearly 100% of the releases to streams were related to direct releases. Tritiated water is more hazardous biologically than tritium gas and reacts chemically in living cells, the same as nonradioactive water (CDC SRSHES 1997).

Alpha-emitting and Beta-emitting radionuclides were also released to liquid effluent. Alpha-emitting radionuclide releases from M-Area primarily affected Tim's Branch, which ultimately flows into Upper Three Runs Creek. Fourmile Branch is the stream most affected by alpha- and beta-emitting releases coming from the separation areas and releases from the reactor areas affected all streams with the exception of Upper Three Runs Creek (Till et al. 2001). Steel Creek, Pen Branch, and Lower Three Runs Creek were mainly affected by beta-emitting releases from the reactors. Strontium-90 is a main contributor of beta activity and came primarily from the reactors (Till et al. 2001).

Plutonium was manufactured on SRS in H-Area from fuel rods and in F-Area from targets (Till et al. 2001). Releases at SRS occurred primarily through the discharge of liquid effluent. Iodine-129 (I-129) is a fission product of reactor fuel that has a very long half-life. Most releases occurred during fuel processing (Till et al. 2001). Technetium-99 (Tc-99) was produced in SRS production reactors as a fission byproduct of uranium and plutonium. This radionuclide was released to the environment from the separation areas ventilation systems, the aqueous environment from liquid waste in waste tanks, and the Solid Waste Disposal Facility (WSRC 1993a).

# Introduction

---

At SRS, strontium was a fission product in the reactors, subsequently released from F-area and H-area (WSRC 1998). SRS operations have also released strontium into the environment through normal site operations and equipment failure.

Routine operations at the SRS have released cesium-137 (Cs-137) to the regional environment surrounding the SRS. The most significant releases occurred during the early years of site operation when Cs-137 was released to seepage basins and site streams. The SRS facilities that have documented Cs-137 releases are the production reactors, separation areas, liquid waste facilities, solid waste disposal facility, central shops, heavy water rework facility, saltstone, and the Savannah River National Laboratory.

The Department of Energy (DOE) is self-regulating. Until 1995, the public had to rely solely on DOE to ensure their health and the environment was protected. The DOE formed an Agreement in Principal with the SCDHEC to perform independent environmental monitoring and oversight of the SRS, giving an extra source of information to the public regarding the effectiveness of the DOE monitoring activities. From this agreement, the Environmental Surveillance and Oversight Program (ESOP) of SCDHEC was initiated to supplement and compliment monitoring and regulatory functions of this unique facility. ESOP provides an added protection due to the potential for catastrophic environmental releases that pose a threat to the state.

Program development at SRS is stable and evolves based on changing missions at the Savannah River Site. The primary focus is on legacy waste and materials that are stored or have been disposed of on-site, and pose a current risk of release to the environment. This report provides information of sample results collected, trending to document how contaminants are changing, and on how these changes may impact the surrounding communities. ESOP will continue its mission of monitoring and oversight around SRS to ensure their on-going activities continue to be safe for the public and the environment.

### 1.1.0 PROJECT SUMMARY

Atmospheric transport has a significant potential to impact the citizens of South Carolina from releases associated with activities at the Savannah River Site (SRS). This project provides independent quantitative monitoring of atmospheric radionuclide releases associated with SRS. This provides monitoring of atmospheric media on a routine basis to measure radionuclide concentrations in the surrounding environment and to identify trends that may require further investigation. Radiological atmospheric monitoring sites were established to provide spatial coverage of the project area.

The South Carolina Department of Health and Environmental Control (SCDHEC) Environmental Surveillance and Oversight Program (ESOP) air monitoring capabilities in 2014 included eight air-monitoring stations with the capacity for sample collection using glass fiber filters, rain collection pans, silica gel columns, and 19 thermoluminescent dosimeters (TLDs). Five of the air-monitoring stations are on or within two miles of the SRS perimeter: New Ellenton (NEL), Jackson (JAK), Allendale Barricade (ABR), South Carolina Advanced Technology Park in Snelling (SCT), and Dark Horse at the Williston Barricade (DKH); one is located at the center of the site, Burial Grounds North (BGN); and two are within 25 miles of the site -Aiken (AIK) and Allendale (ALN). Thirteen of the TLDs are on or near the site perimeter, one is in the center of the site, and five are within 25 miles of the site in surrounding population centers. Only perimeter air monitoring stations and TLDs are used for comparison to SRS data. Refer to Map 1 in Section 4.0 for specific monitoring locations.

The glass fiber filters were used to collect total suspended particulates (TSP). Particulates were screened weekly for gross alpha and gross beta-emitting activity. Precipitation, when present, was sampled and analyzed monthly for tritium. Silica gel distillates of atmospheric moisture were analyzed monthly for tritium. TLDs were collected and analyzed every quarter for ambient beta/gamma levels. First quarter filter samples were analyzed for Plutonium-238 and 239/240 (Pu-238, Pu-239/40). SCDHEC emphasizes monitoring for radionuclides in atmospheric media around SRS at potential public exposure locations.

SCDHEC data substantiated historically reported Department of Energy-Savannah River (DOE-SR) values for radionuclides in the ambient environment at or near the SRS boundary. Average DOE-SR atmospheric radiological monitoring results for gross alpha/beta in air, ambient beta/gamma, and tritium in precipitation at the SRS boundary were within two standard deviations of the SCDHEC reported average values. Variations in atmospheric radiological monitoring results between SCDHEC and DOE-SR are likely a result of differences in monitoring locations, local meteorological conditions, frequency of sampling, and number of locations. Reported differences are for regional background levels and present no difference with regard to the impact on public health.

In summary, no United States Environmental Protection Agency (USEPA) air standards were exceeded at the monitored locations. Sampling results by SCDHEC indicate that SRS activities had a measurable but negligible impact on local air quality.

## 1.2.0 RESULTS AND DISCUSSION

### 1.2.1 Total Suspended Particulates

#### Gross Alpha

During the 2014 sampling period, gross alpha activity ranged from less than the lower limit of detection (<LLD) to 0.0081 picocuries per cubic meter (pCi/m<sup>3</sup>) at the site perimeter (NEL, JAK, ABR, SCT, and DKH). The maximum gross alpha detection was collected on May 13 at the DKH air station. Values in this range are typically associated with naturally occurring alpha-emitting radionuclides, primarily as decay products of radon, and are considered normal (Kathren 1984). The SCDHEC average gross alpha radionuclide concentration in 2014 was 0.0028 ( $\pm$  0.0017) pCi/m<sup>3</sup>. The DOE-SR gross alpha average of 0.0009 ( $\pm$  0.0003) pCi/m<sup>3</sup> is within one standard deviation of the SCDHEC gross alpha activity average (SRNS 2015). Section 5.0, Figure 1 shows average gross alpha activity for SRS perimeter locations and illustrates trending of gross alpha values for SCDHEC and DOE-SR. Figures 6-8 show SCDHEC 2014 trending.

#### Gross Beta

During the 2014 sampling period, the site perimeter (NEL, JAK, ABR, SCT, and DKH) gross beta concentrations ranged from 0.0071 to 0.0387 pCi/m<sup>3</sup>. The maximum gross beta detection was collected on December 22 at the JAK air station. The average gross beta concentration reported by SCDHEC in 2014 was 0.0210 ( $\pm$  0.0059) pCi/m<sup>3</sup>. Section 5.0, Figures 6 - 11 show SCDHEC trending for 2014 for both gross alpha and gross beta. Values in this range are typically associated with naturally occurring beta-emitting radionuclides, primarily as decay products of radon (Kathren 1984). Small seasonal variations at each monitoring location have been consistent with historically reported SCDHEC values (SCDHEC 1999-2015:2013). The USEPA Office of Radiation and Indoor Air uses gross beta counts as an indicator to determine if additional analyses will be performed. A gamma scan is conducted if the gross beta activity exceeds 1 pCi/m<sup>3</sup> (USEPA 2013). This tiering of definitive analyses is used for all total suspended particulate sampling associated with RadNet. RadNet is comprised of a nationwide network of sampling stations that identify trends in the accumulation of long-lived radionuclides in the environment (USEPA 2005). The DOE-SR gross beta average of 0.0133 ( $\pm$  0.0042) pCi/m<sup>3</sup> is within two standard deviations of the SCDHEC gross beta activity average (SRNS 2015). Section 5.0, Figure 2 shows average gross beta activity for the SRS perimeter locations and illustrates trending of gross beta values for SCDHEC and DOE-SR. Figures 9-11 show SCDHEC 2014 trending.

#### Radiochemical Particulate Data

First quarter glass fiber filters were composited and analyzed for Pu-238 and Pu-239/240. No perimeter locations had detections of either Pu-238 or 239/240. However Pu-238 was detected in the Aiken, SC sample.

### 1.2.2 Ambient Beta/Gamma

SCDHEC conducts ambient beta/gamma monitoring through the deployment of TLDs around the perimeter of the SRS. Ambient beta/gamma levels measured with TLDs are provided for all quarters of 2014. It should be noted that 4 millirem (mrem) are subtracted from the reported result for each TLD to account for the transcontinental flight from South Carolina to California and back (Walter 1995). During the 2014 sampling period, yearly ambient beta/gamma ranged from 68 to 111 mrem at the site perimeter. The maximum ambient beta/gamma detection was collected at the US 278 at Upper Three Runs Creek location (TLD-17). The SCDHEC average ambient beta/gamma activity for perimeter TLDs in 2014 was 88.62 ( $\pm 12.51$ ) mrem. The DOE-SR average ambient beta/gamma activity was 83.10 ( $\pm 10.32$ ) mrem for 2014 (SRNS 2015). The DOE-SR ambient/beta gamma average was within one standard deviation of the SCDHEC average. During the sampling period, SCDHEC external radiation levels at monitored locations were slightly higher than levels reported by DOE-SR. Over the past six years, there have been no major increases or decreases in the average ambient beta/gamma activity reported by DOE-SR or SCDHEC. Section 5.0, Figure 3 shows trends at the SRS perimeter for averaged ambient beta/gamma values for DOE-SR and SCDHEC.

### 1.2.3 Tritium

Tritium continues to be the predominant radionuclide detected in the perimeter samples. During 2014, DOE-SR released approximately 27,300 Ci of tritium from SRS (SRNS 2015). Most of the tritium detected in SCDHEC perimeter samples may be attributed to the release of tritium from tritium facilities, separation areas, and from diffuse and fugitive sources (SRNS 2015).

#### Tritium In Air

Tritium in air values reported by SCDHEC are the result of using the historical method of calculating an air concentration of tritium based on the upper limit value of absolute humidity (11.5 grams of atmospheric moisture per cubic meter) in the geographic region (NCRP 1984). SCDHEC tritium results greater than the LLD are then converted from picocuries per liter (pCi/L) to pCi/m<sup>3</sup> using the formula:

$$\text{pCi/L} = \frac{\text{pCi/ml}(11.5)}{1000} = \text{pCi/m}^3$$

During the 2014 sampling period, tritium in air ranged from <LLD to 16.3 pCi/m<sup>3</sup>. The maximum perimeter tritium in air activity was collected at the SCT air station in November. The SCDHEC average measured activity for tritium in air was 5.77 ( $\pm 3.69$ ) pCi/m<sup>3</sup>. The SCDHEC average for tritium activity was well below the USEPA equivalent yearly average standard of 20,000 pCi/m<sup>3</sup> for airborne tritium activity (ANL 2007). The DOE-SR average measured value for tritium activity in air at the SRS perimeter was 12.80( $\pm 5.67$ ) pCi/m<sup>3</sup> (SRNS 2015). DOE-SR average measured values for tritium in atmospheric moisture were higher than SCDHEC average measured values for the SRS perimeter (SRNS 2015). The DOE-SR average measured activity for tritium was

within two standard deviations of the SCDHEC measured average. This difference may be attributed to a dilution that occurs when desiccants are used for collecting atmospheric moisture for tritium analysis. Prior to deployment in the field, silica-gel desiccant is dried to remove any moisture. However, a small percentage of water remains in the desiccant. This results in a slight dilution of the collected sample, which is reflected in the distillate. Another factor that may contribute to the lower SCDHEC air tritium values is that only two of the monitoring stations are exactly on the SRS perimeter (property line); while the other three points used for this comparison are located in population centers, approximately two miles from the SRS property line.

Average DOE-SR tritium in air activity was higher than the SCDHEC measured activity but well within the same order-of-magnitude. These variations could be caused by different sampling locations, number of locations, or sample frequency.

Average tritium in air activity at the SRS perimeter reported by SCDHEC for 2014 was higher than reported in 2013 and has fluctuated over the last six years. DOE-SR also reported a slight decrease from 2013 to 2014 with fluctuations over the past six years. Section 5.0, Figure 4 illustrates trending of atmospheric tritium activity for SCDHEC and DOE-SR as measured and calculated at the SRS perimeter. Section 5.0, Figures 12-14 show SCDHEC 2014 trending.

#### Tritium In Precipitation

During the 2014 sampling period, tritium in precipitation ranged from <LLD to 333 pCi/L. The maximum reported value for SCDHEC perimeter locations was collected at the DKH air station in May. The SCDHEC average measured activity for tritium in precipitation was 275 ( $\pm$  54) pCi/L. The DOE-SR average measured value for tritium activity in precipitation at the SRS perimeter was 741( $\pm$  336) pCi/L (SRNS 2015). The SCDHEC and DOE-SR averages for tritium activity were well below the USEPA standard of 20,000 pCi/L in drinking water (USEPA 2002b). The DOE-SR averages for tritium activity were within one standard deviation of the SCDHEC average. Section 5.0, Figure 5 shows average tritium in precipitation activity for SRS perimeter locations and illustrates trending tritium in precipitation values for SCDHEC and DOE-SR. Section 5.0, Figures 15 - 17 show trending for 2014 for SCDHEC.

### **1.3.0 CONCLUSIONS/RECOMMENDATIONS**

All SCDHEC data collected in 2014 confirmed historically reported DOE-SR values for gross alpha/beta, ambient beta/gamma, and tritium in the environment at the SRS boundary, with no anomalous data noted for any monitored parameters.

Even with the variability of environmental data and sampling frequencies, DOE-SR gross alpha/beta in air, tritium in precipitation, tritium in air, and ambient beta/gamma averages were within two standard deviations of SCDHEC measured averages.

No USEPA air standards were exceeded at the monitored locations. Sampling results by SCDHEC indicate that SRS activities did have a measurable but negligible impact on local air

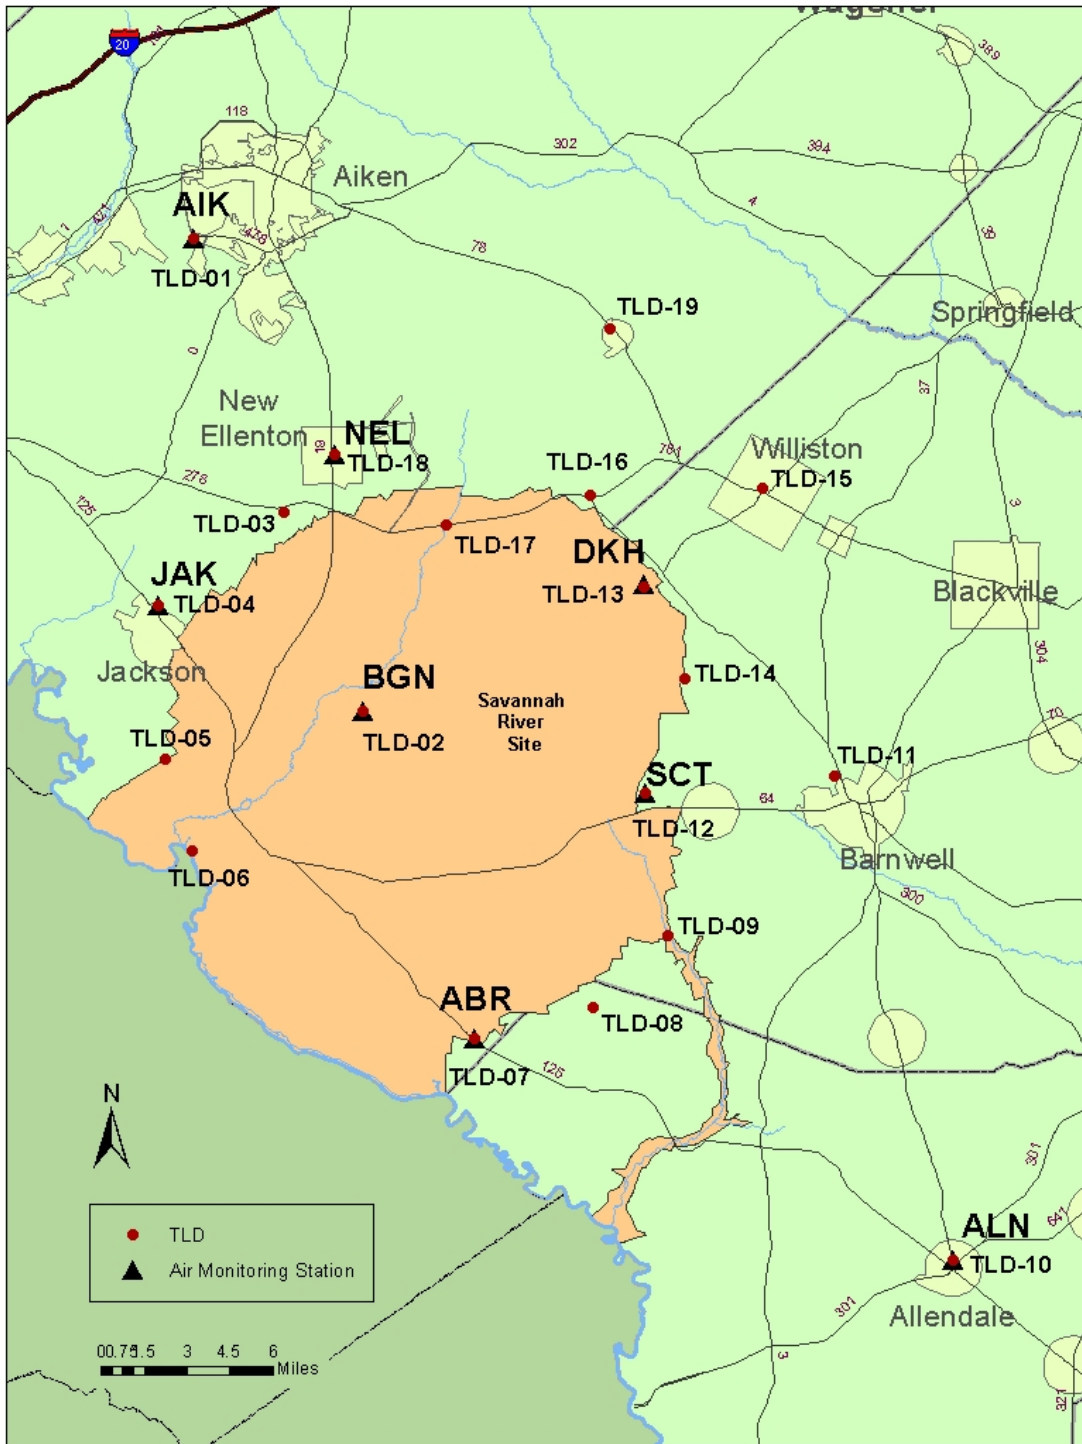

quality.

Due to continued releases from site facilities (tritium facilities, separations areas, etc.), SCDHEC will continue to collect weekly TSP for gross alpha/beta, monthly for atmospheric and precipitation tritium, and quarterly ambient beta/gamma samples.

# 2014 Ambient Groundwater Monitoring Adjacent to the Savannah River Site

## Environmental Surveillance and Oversight Program

96GW003

Shane S. Shull, Project Manager

January 01, 2014 - December 31, 2014

Midlands EQC Region - Aiken  
206 Beaufort Street N.E.  
Aiken, SC 29801

South Carolina Department of Health  
and Environmental Control

### 2.1.0 PROJECT SUMMARY

The Environmental Surveillance and Oversight Program (ESOP) of the South Carolina Department of Health and Environmental Control (SCDHEC) samples an ambient groundwater monitoring network adjacent to the Savannah River Site (SRS) to characterize groundwater quality in the area. This annual evaluation is conducted to determine possible offsite groundwater impacts due to operations conducted at the SRS. ESOP provides this project report annually as an independent source of information concerning Department of Energy-Savannah River (DOE-SR) activities and the potential impacts of those activities to public health and the environment.

SCDHEC currently utilizes a regional groundwater monitoring well network consisting of cluster wells (C-wells) and network wells (consisting of private wells and public water systems). This groundwater well network consists of approximately 75 wells that are routinely sampled by SCDHEC. The C-wells are owned and maintained by the South Carolina Department of Natural Resources (SCDNR). These cluster wells are screened from shallow surficial aquifers to depths exceeding 1,400 feet below ground surface. The C-well clusters are situated throughout the perimeter of the SRS.

The following items outline the objectives of the project, as well as the importance of sampling for radionuclides throughout the groundwater well network:

- Evaluate groundwater quality adjacent to SRS;
- Compare results with historical data;
- Determine any SRS contaminant migration offsite;
- Expand current ambient water quality databases;
- Provide the public with independently generated, region specific, groundwater quality information.

The study area is composed of a 10-mile perimeter extending from the SRS boundary, as well as random background locations found throughout the state of South Carolina. The 10-mile sampling perimeter was selected based on groundwater well availability and overall proximity to the SRS. As part of the ongoing ambient groundwater study, sampling of random background (B locations) will continue throughout the state of South Carolina. These sample locations are selected at random using a designated quadrant system that extends throughout the state of South Carolina. These samples are collected from either private or municipal groundwater wells. The project map in Section 4.0 depicts the network groundwater well locations, the extent of the study area, and the wells sampled during the 2014 sampling event. ESOP evaluates five aquifer zones (Upper Three Runs, Gordon, Crouch Branch, McQueen Branch, and the Piedmont Hydrogeologic Province) from the water table to confined aquifers more than 1,400 feet deep (Section 5.0, Table 2).

The SCDHEC analytical laboratory data from the 2014 groundwater sampling event revealed limited contaminants present in the groundwater wells sampled. These groundwater wells, along with the extent of contaminants, will be detailed in Section 2.0 of this report. Due to the low concentrations and limited extent of the contaminants identified in these groundwater wells, it is

likely the sources of these contaminants are a result of naturally occurring processes in the subsurface.

### 2.2.0 RESULTS AND DISCUSSION

The 2014 groundwater sampling event was scheduled for sample collection from 18 C-wells and two private wells. All wells scheduled for sampling in 2014 were successfully sampled and no issues were encountered. Additionally, three background samples were collected at random locations in South Carolina. The project map features sampling locations, and can be found in Section 4.0. Based on a review of the wet chemistry, metals, tritium, gross alpha, non-volatile beta, and gamma-emitting radioisotope analytical data provided by the SCDHEC analytical and radiological laboratories, various contaminants were detected in 16 of the groundwater wells sampled. Please see Section 5.0, Table 1 for a list of all wells, their locations, and sampling schedule. To view the electronic groundwater data set, please see *Appendix A - ESOP Data*.

Alpha activity was detected in three C-Wells (GWM03706, GWM03707 and GWM03709) and one private well (GWD00383) during the 2014 sampling event. None of the alpha detections exceeded the United States Environmental Protection Agency (USEPA) maximum contaminant level (MCL) of 15 picocuries per liter (pCi/L) (USEPA 2002b). Tritium was detected in two private wells (GWD00383 and GWD02640), but activities were well below the USEPA drinking water MCL of 20,000 pCi/L (USEPA 2002b). Non-volatile beta was detected at two of the C-wells sampled (GWM03707 and GWM03709). Non-volatile beta activities did not exceed the USEPA MCL of 50 pCi/L (USEPA 2002b).

The 2014 groundwater sampling event revealed additional contamination in several groundwater well locations. One or more of the following contaminants: nitrate/nitrite, barium, and lead were detected in 16 well locations (GWD00383, GWD02640, GWM03131, GWM03132, GWM03702, GWM03703, GWM03704, GWM03705, GWM03706, GWM03707, GWM03708, GWM03709, GWM06601, GWM06602, GWM06605 and GWM06608). None of the detected contaminants exceeded their respective USEPA established MCLs or action levels for drinking water.

The 2014 groundwater analytical data suggests the extent of the contaminants are isolated and likely the result of dissolved metals and radionuclides from naturally occurring geologic formations.

Contaminants commonly found in the SRS groundwater include: volatile organic compounds, metals, and tritium. In the event known contaminants (commonly found in SRS groundwater) are found in wells located within the SCDHEC sampling network, the affected wells would be investigated further to help determine the source. Due to the extensive groundwater contamination on SRS, SCDHEC will continue to monitor groundwater quality to identify any future SRS offsite contaminant migration.

### **2.2.1 Radiological Parameter Results**

The presence of naturally occurring radionuclides has been well documented in the groundwater regime across the state of South Carolina. Groundwater investigations performed by state and federal agencies such as SCDHEC, SCDNR, and the United States Geological Survey (USGS) have confirmed the presence of these radionuclides (ATSDR 2007).

Gross alpha was detected at four of 18 groundwater wells sampled during the 2014 event (Figure 1). These locations are identified as C-Wells (GWM03706, GWM03707 and GWM03709) and private well (GWD00383). Gross alpha activities at these locations were 3.02 pCi/L, 2.52 pCi/L, 6.05 pCi/L and 3.16 pCi/L respectively. None of these locations exceeded the USEPA drinking water limit of 15 pCi/L (USEPA 2002b).

Non-volatile beta was detected in two of the groundwater wells sampled (Figure 2). These two locations (C-wells) are identified as GWM03707 and GWM03709 and yielded activities of 5.16 pCi/L and 3.14 pCi/L respectively. Both samples were below the established MCL of 50 pCi/L for non-volatile beta (USEPA 2002b).

Tritium was detected at low levels in two private wells, GWD00383 and GWD02640. Activities in these two samples were 257.06 pCi/L and 245.70 pCi/L. These activities are below the USEPA drinking water MCL of 20,000 pCi/L (USEPA 2002b). Due to the known tritium groundwater contamination on SRS and the overall concern from local stakeholders, sampling for Tritium will continue and be addressed in all future project reports.

Gamma analysis was conducted for all groundwater samples during the 2014 sampling event. All samples were below the Minimum Detectable Activity (MDA) for gamma in 2014. Gamma analyses will continue to be conducted for future groundwater sampling events.

### **2.2.2 Nonradiological Parameter Results**

The presence of metals and other nonradiological contaminants in the environment can be attributed to man-made processes such as industrial manufacturing and/or the natural decay of deposits. However, a review of the following metal and nonradiological contaminants detected indicates their limited presence and concentration is most likely due to the erosion of natural deposits. Additionally, the position of these wells, as related to the SRS's centrally located process areas suggests the theory of natural occurrence. All analytical results can be found in *Appendix A - ESOP Data*.

During the 2014 groundwater sampling event, samples were collected for volatile organic compounds (VOCs). No VOCs were detected at any of the sampling locations in 2014.

Barium was detected at 11 C-Well locations, (GWM03131, GWM03132, GWM03703, GWM03704, GWM03705, GWM03706, GWM03707, GWM03708, GWM03709, GWM06605 and GWM06608) with concentrations of 0.120 milligrams per liter (mg/L), 0.180 mg/L, 0.170 mg/L, 0.190 mg/L, 0.091 mg/L, 0.086 mg/L, 0.110 mg/L, 0.130 mg/L, 0.120 mg/L, 0.150 mg/L and 0.110 mg/L respectively. Calculations revealed a barium average of 0.132 mg/L in these

groundwater well locations. Although the concentration of barium in these wells is detectable, they do not exceed the 2.00 mg/L MCL established by the USEPA (USEPA 2002b). As a result, these concentrations are not considered known risks to human health.

Lead was detected in one C-Well (GWM03703) yielding a concentration of 0.0090 mg/L. The lead level detected in this well was below the USEPA established action level for lead of 0.015 mg/L. Elevated lead levels in groundwater wells are often the result of naturally occurring deposits (ATSDR 2007).

Nitrate/Nitrite was detected at concentrations below the 10 mg/L MCL (USEPA 2002) in 3 C-Wells (GWM03702, GWM06601 and GWM06602) and 2 private wells (GWD00383 and GWD02640), yielding concentrations of 0.053 mg/L, 0.280 mg/L, 0.100 mg/L, 0.560 mg/L and 0.750 mg/L respectively. Calculations revealed a nitrate/nitrite average of 0.349 mg/L in these five groundwater well locations. The presence of nitrate/nitrite is most likely due to the erosion of natural deposits and/or runoff from fertilizer use. Once in the soil, nitrate is mobile due to its high water solubility, and, therefore, moves easily through the soil at a speed comparable to the local groundwater flow velocity (USGS 1998).

### 2.2.3 ESOP and DOE-SR Data Comparison

Due to the fact DOE-SR collects groundwater samples from a separate onsite monitoring well network, direct SCDHEC offsite groundwater comparisons could not be made to their findings in the latest SRS Environmental Report for 2014. However, the 2014 SRS report identifies numerous areas of groundwater contamination throughout the SRS property. These areas of impacted groundwater include A-Area, C-Area, D-Area, E-Area, F-Area, H-Area, K-Area, L-Area, M-Area, P-Area, R-Area, Z-Area, Sanitary Landfill, TNX, and Chemicals Metals Pesticides (CMP) pits. The extent of the contamination varies and some of the contaminants include: various volatile organic compounds (VOCs), tritium, gross alpha, beta radionuclides, and strontium-90 (SRNS 2015). Contaminants detected in the 2014 SCDHEC groundwater sampling event include gross alpha, non-volatile beta, tritium, barium, nitrate/nitrite and lead. Due to the presence of the aforementioned contaminants in the groundwater on the SRS, the ESOP groundwater monitoring project will continue sampling for these and other contaminants in future sampling events.

### 2.2.4 Summary Statistics

During the 2014 groundwater sampling event, 23 wells were sampled. Of these 23 wells, 18 are classified as C-wells, two are private wells and three are classified as random background wells.

Laboratory analytical data revealed an average tritium activity of 251.38 ( $\pm 8.03$ ) pCi/L. Tritium was detected in two of 23 groundwater samples, in private wells GWD00383 and GWD02640. These wells are located in the vicinity of Jackson, SC. Both detections were below the USEPA drinking water MCL of 20,000 pCi/L (USEPA 2002b).

Gross alpha was detected at an average activity of 3.69 ( $\pm$  1.60) pCi/L, based on four detections in wells GWD00383, GWM03706, GWM03707 and GWM03709. None of the gross alpha detections exceeded the 15 pCi/L safe drinking water limits established by the USEPA.

Summary statistics for non-volatile beta in groundwater wells samples revealed an average activity of 4.15 ( $\pm$  1.43) pCi/L, based on two detections in wells GWM03707 and GWM03709.

Gamma was not detected in any groundwater samples collected in 2014.

Radionuclides were not detected above the detection limit in any of the samples collected from the three random background locations.

### **2.3.0 CONCLUSIONS AND RECOMMENDATIONS**

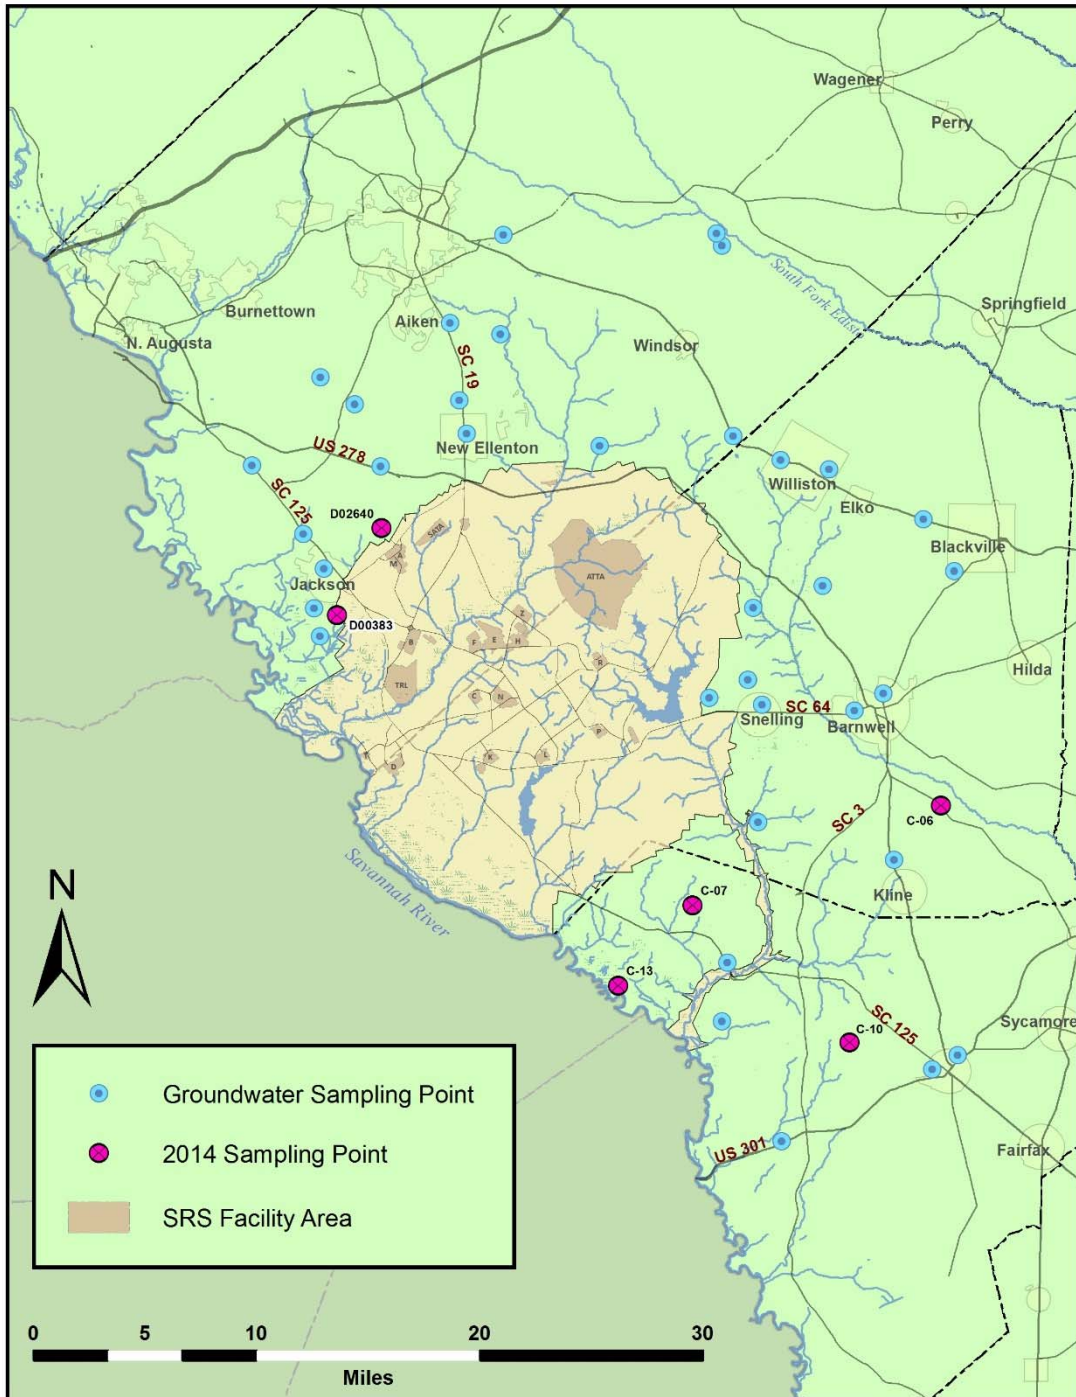

A review of the 2014 analytical data revealed various but limited nonradiological and/or radiological constituents in the majority of the 23 groundwater wells sampled. Although several of the wells sampled during this event revealed detectable concentrations, the data suggests the extent of the contaminants is isolated and likely the result of dissolved metals and radionuclides from naturally occurring geologic formations.

The Ambient Groundwater Quality Monitoring Project (AGQMP) attempted to determine if constituents, other than naturally occurring, have impacted groundwater within the monitoring network. The results of the 2014 groundwater sampling event indicate several nonradiological constituents and naturally occurring radionuclides are impacting groundwater quality in isolated regions throughout the groundwater monitoring well network. Independent monitoring of basic water quality parameters, metals, VOCs, tritium, gross alpha, non-volatile beta, and gamma-emitting radionuclides will continue throughout future annual groundwater investigations. In addition, statistical analysis of background data along with evaluating DOE-SR groundwater monitoring data, will be performed. Continued groundwater monitoring will provide a better understanding of actual groundwater quality parameters, their extent, and trends. As a result, comparisons with historical data can be made. In addition, ESOP will provide SCDHEC's Bureau of Water with groundwater data to assist in their evaluation of the extent of naturally occurring radionuclides in the region.

During future DOE-SR ambient groundwater sampling events (using the SRS P-wells), SCDHEC will request the opportunity to conduct split QA/QC (Quality Assurance/Quality Control) sampling. The term P-Wells is used to describe the groundwater monitoring well network used to sample groundwater within the SRS site boundary. Split sampling at random well locations throughout the SRS groundwater well network will help provide SCDHEC further annual confirmation.

**2.7.0 Regional Geology**

The study area, including SRS, is located in west-central South Carolina. The regional geology is characterized as the Aiken Plateau of the Coastal Plain physiographic province. SRS is located approximately 20 miles southeast of the fall line of the Piedmont physiographic province. A thickening wedge of Cenozoic and Cretaceous sediment, which overlies Paleozoic crystalline basement rock and Triassic sedimentary rocks, underlies the area south of the fall line (Aadland et al 1995). The sediment, consisting of alternating sands and clays with Tertiary carbonates, thickens toward the southeast from zero at the fall line to more than 1,800 feet at the Allendale-Hampton County line. The sediment is about 1,100 feet thick beneath the central portion of SRS and dips toward the southeast at about 35 feet per mile. Table 2 in Section 5.0 summarizes the stratigraphy and hydrostratigraphy of the study area. For a more detailed review of regional geology and hydrogeology, refer to the 1997 Annual Report (SCDHEC 1999-2015:1999).

# 2014 Radiological Monitoring of Drinking Water Adjacent to the Savannah River Site

## Environmental Surveillance and Oversight Program

97DW006

Shane S. Shull, Project Manager

January 01, 2014 - December 31, 2014

Midlands EQC Region - Aiken  
206 Beaufort Street N.E.  
Aiken, SC 29801

South Carolina Department of Health  
and Environmental Control

### 3.1.0 PROJECT SUMMARY

The Environmental Surveillance and Oversight Program (ESOP) Drinking Water Monitoring Project, as part of South Carolina Department of Health and Environmental Control (SCDHEC), evaluates drinking water quality in communities that could potentially be impacted by Savannah River Site (SRS) operations. ESOP monitoring provides information to the public regarding the extent that radiological constituents may or may not have impacted community drinking water systems adjacent and downstream of SRS. Additionally, ESOP provides analytical data from this project for comparison to published Department of Energy-Savannah River (DOE-SR) data. The project objectives are to collect monthly composite surface water samples from one location upstream from the SRS (North Augusta) as well as three locations downstream from SRS (Purrysburg Beaufort/Jasper (B/J), Chelsea B/J, and Savannah, GA). Additionally, semi-annual grab samples are collected from selected public drinking water systems within 30 miles from the center point of the SRS. SCDHEC analyzes all samples for gross alpha, non-volatile beta, gamma-emitting radionuclides, and tritium. Non-detect values are not included when calculating averages for each analyte.

The study area was established as a 30-mile radius circle centered on SRS. The 30-mile sampling perimeter was selected based on drinking water system availability and overall proximity to SRS. Using SCDHEC geographical information systems, nineteen primarily groundwater fed and four surface water fed public drinking water systems were selected (Section 4.0, Map). These sample locations were selected specifically to help ensure complete sample coverage around the SRS perimeter. These water systems serve approximately 281,000 customers with approximately 105,000 receiving their water from groundwater sources (Section 5.0, Table 1). None of the drinking water samples collected originated from the SRS drinking water system.

As part of the drinking water project, sampling of random background locations, also known as Drinking Water Background (DWB) samples, will continue throughout the state of South Carolina. Sample locations are selected at random using a designated quadrant system that extends throughout the state. Once a random set of quadrants have been selected, samples are collected from identifiable public drinking water systems within the quadrants.

During 2014, DOE-SR collected surface water samples from two locations (North Augusta and Chelsea B/J) that are colocated with the ESOP surface water fed drinking water systems. Currently, DOE-SR does not conduct drinking water sampling from groundwater fed wells off-site.

Historically, tritium has been the primary environmental release due to operations at SRS. Tritium was produced as a nuclear weapon enhancement component. The majority of tritium releases came from the production reactors and the separation areas (Till et al 2001). In addition to SRS activities, tritium can potentially be attributed to releases from other nuclear facilities within close proximity of the study area.

Man-made gamma-emitting radionuclides, such as iodine-131, cesium-137, and cobalt-60, were products of SRS activities. These radionuclides were produced by fission in reactor fuels and

were primarily released in surface streams in the 1960s or into the atmosphere in the separation areas (WSRC 1998).

### 3.2.0 RESULTS AND DISCUSSION

#### 3.2.1 Surface Water System Network Results

##### Tritium

Historically, the primary tritium releases originated from processes associated with the reactors (R, P, K, L, and C), separation facilities (F-area and H-area), the heavy water facility (D-area), and tritium recovery in the tritium facilities. The main types of tritium releases originate from site facilities, migration from seepage basins in F-area and H-area, the burial ground, and the K-area containment basin. In the early operational years, nearly 100% of the releases to streams were related to direct releases. After the cessation of operational activities, most releases were a result of migration from the seepage basins. Since the mid 1970s, migration and outcropping to streams have accounted for most of the SRS tritium released to surface water (Till et al. 2001).

Tritium is naturally present in surface waters at 10 to 30 picocuries per liter (pCi/L) (ANL 2007). The maximum contaminant level (MCL) developed by the United States Environmental Protection Agency (USEPA) for tritium in drinking water is an average of 20,000 pCi of tritium per liter of water, over the course of a year. Tritium continues to be the most abundant radionuclide detected in public drinking water in the study area (see *Appendix A - ESOP Data*). During 2014, tritium was detected in surface water fed systems only. The ESOP tritium detectable average was 423.57 ( $\pm$  170.27) pCi/L. The DOE-SR detectable average for surface water systems was 263 ( $\pm$  14.90) pCi/L (SRNS 2015). This activity is well below the USEPA established 20,000 pCi/L drinking water limit (USEPA 2002b). To view ESOP drinking water data, please access the electronic file *Appendix A - ESOP Data*.

Based on a review of the surface water data from the Savannah River, tritium was detected above the lower limit of detection (LLD) in approximately 58.33% of surface water composite samples. The LLD range for tritium in 2014 was 218 pCi/L to 246 pCi/L. Detectable tritium activity in these samples yielded an average of 423.57 ( $\pm$  170.27) pCi/L and ranged from 247 to 945 pCi/L. These tritium activities are measurable but not significant when compared to the 20,000 pCi/L USEPA MCL (USEPA 2002b). There were no detections above the LLD for tritium in any of the 12 upstream North Augusta surface water composites. Of the 36 composite samples collected downstream from the SRS, 28 samples had a tritium activity above the LLD. The tritium activity in these three downstream intakes (Chelsea B/J, Purrysburg B/J, and Savannah) had a range of 247 to 945 and averaged 423.57 ( $\pm$  82.61) pCi/L. Figure 1 of Section 5.0 illustrates the trending data for surface water fed systems over the past five years.

Three background samples were also collected during the 2014 sampling event. Laboratory results revealed a single tritium detection of 463 pCi/L at DWB-3 in Belton, SC. This activity was well below the 20,000 pCi/L USEPA drinking water.

### Gamma-emitting Radionuclides

Gamma-emitting radionuclides of concern (Section 5.0, Table 2) were not detected above the LLD and have not been detected for any of the surface water samples collected by ESOP or DOE-SR since 2002.

### Gross Alpha and Non-volatile Beta

Gross alpha-emitting radionuclides were released to liquid effluent from the reactor materials area (M-area), separations areas (F-area and H-area), and the reactor areas. The primary stream affected by the M-area releases was Tims Branch, that ultimately flows into Upper Three Runs. Fourmile Creek is the stream most affected by releases coming from the separation areas. Releases from the reactor areas affected all streams with the exception of Upper Three Runs (Till et al 2001). Gross non-volatile beta-emitting radionuclides were released to liquid effluent from the separations areas (F-area and H-area). The aforementioned streams ultimately flow directly or indirectly into the Savannah River.

Gross alpha was detected in North Augusta, Purrysburg B/J, and Savannah samples with an average activity of 6.06 ( $\pm$  2.41) pCi/L and ranged from 3.59 to 8.40 pCi/L. Non-volatile beta was detected at two sample locations (North Augusta and Chelsea B/J). These two locations revealed non-volatile beta detections that averaged 4.97 ( $\pm$  0.22) pCi/L and ranged from 4.81 to 5.12 pCi/L. Speciation is not conducted for gross alpha or non-volatile beta unless there is a detection above their respective USEPA MCLs of 15 pCi/L and 50 pCi/L (USEPA 2002). Alpha and beta activity is likely attributable to naturally occurring radionuclides.

Section 5.0 (Figures 2 and 3) illustrates the trends in gross alpha and non-volatile beta activities since the year 2009. Although there are several detections identified during the 2014 sampling event, none of these analytes have exceeded the USEPA established MCL for each of these contaminants. As a result, these concentrations are not considered to be known human health risks.

### **3.2.2 Groundwater System Network Results**

#### Tritium

Based on a review of the analytical data, none of the 19 groundwater fed systems sampled had tritium activities above the LLD. Figure 1 in Section 5.0 shows trending data from the past five years for the samples from groundwater fed systems that showed detections.

#### Gamma-emitting Radionuclides

Gamma-emitting radionuclides of concern were not detected above the LLD in any groundwater samples tested in 11 years of testing by ESOP. As a result of the history of non-detections for gamma-emitting radionuclides, no summary statistics were calculated (Section 6.0).

### Gross Alpha and Non-volatile Beta

Gross alpha was detected in 5 of the 19 primarily groundwater fed systems (Langley, Talatha, Montmorenci, Williston and SCAT Park) tested in 2014. The range for gross alpha activity was 1.97 to 10.30 pCi/L with an average activity of 4.76 ( $\pm$  3.45) pCi/L. All gross alpha samples were below the USEPA MCL of 15 pCi/L (USEPA 2002). Speciation is not conducted for gross alpha unless there is a detection above the USEPA MCL of 15 pCi/L. Summary statistics for groundwater fed systems are located in Section 6.

Non-volatile beta was not detected above the LLD in any of the 19 groundwater systems tested in 2014. The USEPA MCL for non-volatile beta is 50 pCi/L (USEPA 2002). Speciation would be conducted for non-volatile beta if any detections were made above the USEPA MCL.

### **3.3.3 Background Sample Results**

During the 2014 drinking water sampling event, three background samples were collected at random throughout the state of South Carolina (DWB-1, DWB-2, DWB-3). Each of these samples were tested for gross alpha, non-volatile beta, gamma, and tritium. Laboratory results revealed a single detection for tritium of 463 pCi/L at DWB-3 in Belton, SC. Although this activity is detectable, it is well below the USEPA established 20,000 pCi/L drinking water limit.

### **3.3.4 ESOP and DOE-SR Data Comparison**

DOE-SR conducts monthly composite sampling at two water treatment plants (North Augusta and Chelsea B/J) that use Savannah River surface water to supply drinking water for the local population.

Based on the DOE-SR 2014 annual report (SRNS 2015), tritium in the downstream water intake averaged 263 ( $\pm$  14.90) pCi/L ranging from 104 to 559 pCi/L while ESOP downstream detections averaged 423.57 ( $\pm$  170.27.20) pCi/L ranging from 247 to 945 pCi/L. Figure 4 and Figure 5 illustrate DOE-SR finished water tritium detection averages over a five year time period. DOE-SR had an overall detected tritium average of 182.41 ( $\pm$  126.77) pCi/L for all surface water samples collected in 2014. This was lower than the ESOP detected tritium average of 423.57 ( $\pm$  170.27) pCi/L for the same period. ESOP sampling did not detect tritium above the LLD for the North Augusta location during 2014. Due to the fact North Augusta is located upstream from the SRS, tritium activities are expected to be much lower at this location (Section 5.0, Table 3). All samples were within two standard deviations as well as being lower than the USEPA MCL of 20,000 pCi/L (USEPA 2002). Tritium activity in 2014 is within two standard deviations of the running 5-year average. These activity levels are well below the USEPA MCL. Naturally occurring radionuclides may account for variability in tritium activities. Tritium continues to be the most abundant radionuclide in the Savannah River.

Gamma-emitting radionuclides were not detected in DOE-SR or ESOP samples in 2014. DOE-SR and ESOP detected non-volatile beta in surface water samples. The DOE-SR non-volatile beta average (for all locations) of 2.11 ( $\pm$  0.31) pCi/L was less than the ESOP non-volatile beta average (for North Augusta and Chelsea B/J) of 4.97 ( $\pm$  0.22) pCi/L. DOE-SR did not detect gross alpha activity at statistically significant levels during 2014. ESOP had surface

water gross alpha detections at North Augusta, Purrysburg B/J, and Savannah, with an average activity of 6.06 ( $\pm$  2.41) pCi/L. All detections were less than the established USEPA MCL for gross alpha and non-volatile beta in drinking water (USEPA 2002).

Alphas (or betas) are not directly comparable due to the unknown nature (species) of the contributing alphas (or betas) in any two compared samples.

### 3.3.0 CONCLUSIONS AND RECOMMENDATIONS

Tritium continues to be the most abundant radionuclide detected in public drinking water supplies potentially impacted by SRS. Tritium was detected in both groundwater and surface water systems during 2014. Observed tritium activities were low when compared to the USEPA MCL for tritium in drinking water, which is an average of 20,000 pCi of tritium per liter of water, over the course of a year. Detections of gross alpha and non-volatile beta radionuclides of concern were all below their respective MCLs. Comparative analysis with DOE-SR for groundwater systems cannot be performed because DOE-SR does not sample groundwater systems off the Savannah River Site. Due to this fact, it is of great importance that SCDHEC continues to monitor these off-site public water systems in the event these wells are impacted by contaminated groundwater from the SRS (SRNS 2015).

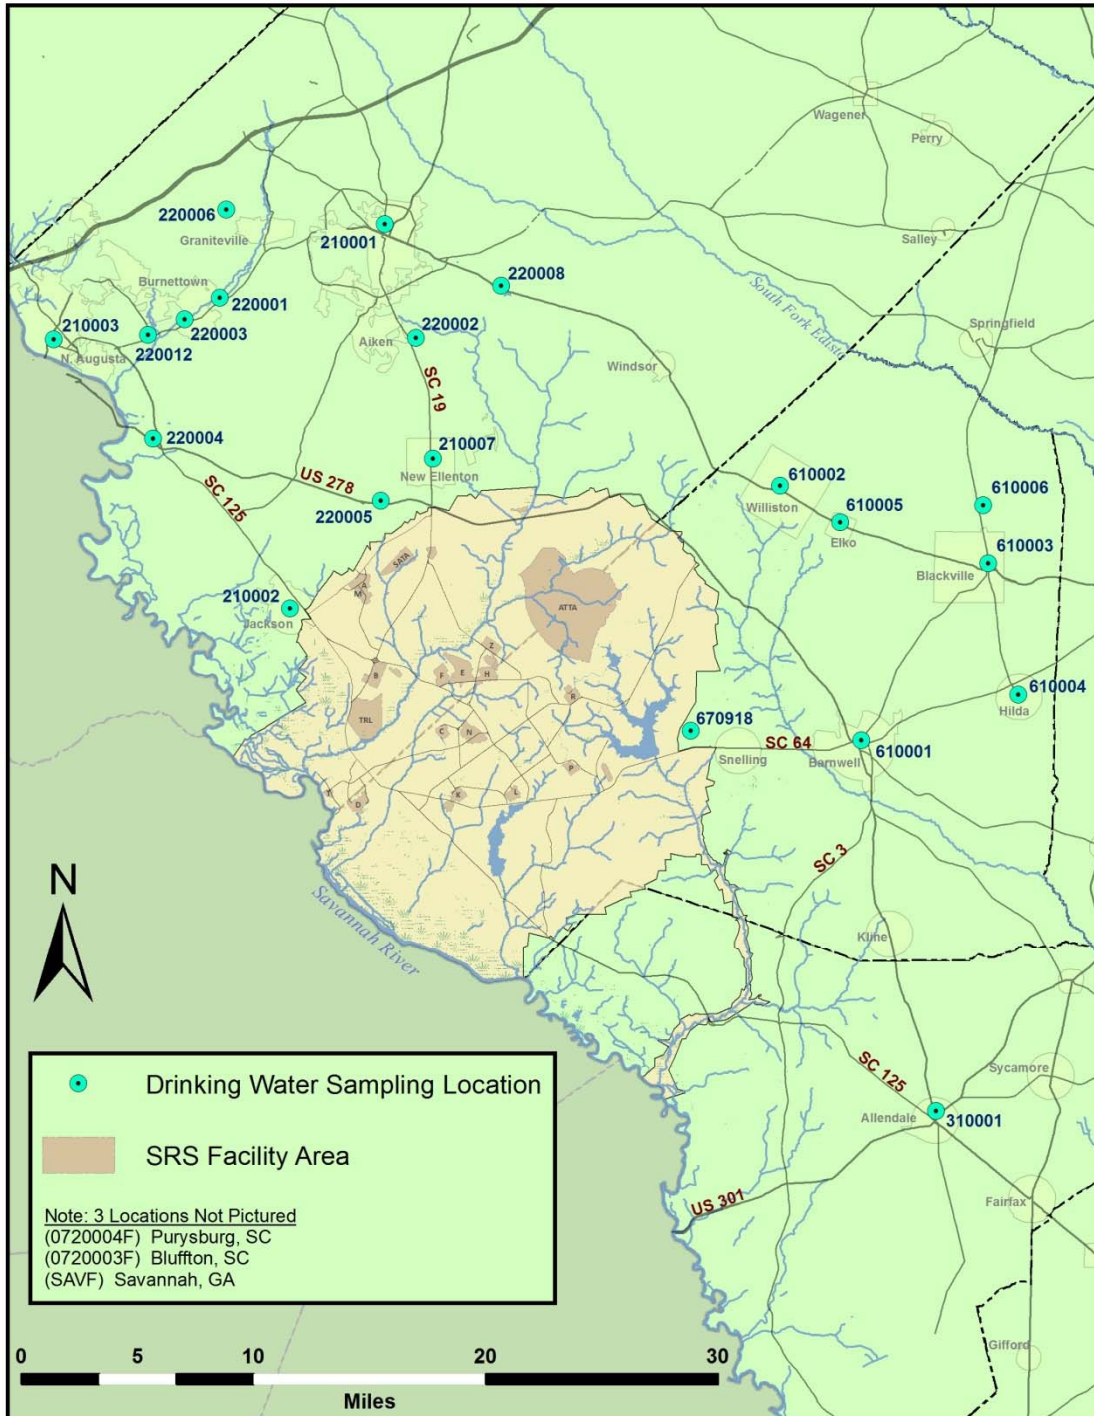

The SCDHEC Drinking Water Monitoring Project continues to be an important source of essential data for assessing human health exposure pathways. SCDHEC will continue to monitor surface water quality due to the extent of the surface water contamination on SRS, and its potential to migrate and potentially impact drinking water systems downstream from SRS. Continued sampling will also provide the public with an independent source of radiological data for drinking water systems within the SRS study area.

SCDHEC will continue collecting background samples to provide a more complete picture of ambient radioactivity levels present in South Carolina. The data from these samples will be used in statistical analyses with the routine samples.

Currently, additional drinking water systems in the area around SRS are being considered for routine sampling. If these locations prove to be beneficial to the drinking water project, they will be added to the project and included in all future sampling events.

# 2014 Radiological Monitoring of Surface Water on and Adjacent to the Savannah River Site

## Environmental Surveillance and Oversight Program

97RW002

Beth Cameron, Project Manager

January 01, 2014 - December 31, 2014

Midlands EQC Region - Aiken  
206 Beaufort Street, NE  
Aiken, SC 29801

South Carolina Department of Health  
and Environmental Control

#### **4.1.0 PROJECT SUMMARY**

The focus of the Radiological Monitoring of Surface Water (RSW) project is monitoring and surveillance of the streams and creeks on the Savannah River Site (SRS) as well as the Savannah River. This project is part of the South Carolina Department of Health and Environmental Control (SCDHEC) Environmental Surveillance and Oversight Program (ESOP). Since the Savannah River is the primary drinking water source for downstream communities, it is important to monitor radionuclide concentrations in the river. Surface water samples are collected and analyzed for radionuclides, and the results are compared to Department of Energy-Savannah River (DOE-SR) data. DOE-SR conducts surveillance and monitoring activities for the following purposes: determining concentrations and migration of radionuclides in the aquatic environment, detecting and verifying accidental releases, characterizing concentration trends, and determining associated impacts on human health and the environment. ESOP supports DOE-SR's objectives to ensure the primary goal of drinking water safety is established and met. These activities will allow the RSW project to generate independent data to compare with DOE-SR data. This data is shared with the public.

The RSW project analyzes water samples for many gamma-emitting radionuclides. Cesium-137 (Cs-137) continues to be the main gamma-emitting radionuclide detected in the SRS streams. The streams that were largely affected by Cs-137 are: Fourmile Branch, Pen Branch, Steel Creek, and Lower Three Runs Creek, with Steel Creek historically showing the highest activity (Till, et al. 2001).

Alpha-emitting radionuclides were released to liquid effluent from M-Area, separation areas, and the reactor areas. The primary stream affected by the M-area releases was Tims Branch, which ultimately flows into Upper Three Runs Creek. Fourmile Branch is the stream most affected by releases coming from the separation areas. Releases from the reactor areas affected all streams with the exception of Upper Three Runs Creek (Till, et al. 2001).

Beta-emitting radionuclides were released to liquid effluent from separation areas and the reactors. Fourmile Branch is the stream primarily affected by releases from the separations areas. Steel Creek, Pen Branch, and Lower Three Runs Creek were mainly affected by releases from the reactors. Strontium-90 (Sr-90) is a main contributor of beta activity and came primarily from the reactors (Till, et al. 2001).

The RSW project continues to collect surface water samples from 13 specific locations within and outside of the SRS boundary as part of an ambient sampling network (Section 4.0, Map). Section 5.0, Table 1, identifies sample ID, location, rationale, and frequency. Seven of these locations use ISCO™ automatic water samplers to collect aliquots every 30 minutes to produce a composite. Grab samples are collected from the remaining six locations. Samples are collected three days per week (Monday, Wednesday, and Friday) from the locations that have automatic water samplers. The composite sampler is utilized to collect composite samples over a 48-hour period (Monday through Wednesday and Wednesday through Friday) or a 72-hour period (Friday through Monday). One sample is poured from the composite for same day tritium analysis. Another sample is poured into a secondary bottle from the composite and combined for the whole week. This weekly composite sample is then combined in a tertiary container to be analyzed monthly for gross alpha, gross beta, and gamma (Table 1.). Some locations were

chosen because they are considered to be public access locations. The public access locations are downstream of SRS, providing a potential means for exposure to radionuclides with the exception of the background location of Jackson Boat Landing (SV-2010).

Quarterly samples are collected for tritium analysis from the four creek mouths that flow from SRS directly into the Savannah River (Upper Three Runs Creek, Fourmile Branch, Steel Creek, and Lower Three Runs Creek). Pen Branch is not sampled because the Savannah River Swamp interrupts the flow for this creek and there is no creek mouth access.

An enhanced surface water monitoring program was implemented to provide downstream drinking water customers with advance notice of the potential for increased tritium levels in the Savannah River due to an SRS release. This early detection facet is possible because of the continuous monitoring of the five SRS streams that flow to the Savannah River. Samples for tritium analysis are collected from seven locations with automatic water samplers. Additionally, a grab sample is collected from Johnson's Boat Landing (SV-2080) and US Highway 301 at the Savannah River (SV-118). Sampling devices at SV-118 consist of an ISCO™ composite sampler and a 24-bottle carousel sampler. The carousel sampler provides hourly samples collected for the same respective time frame as the composite sampler. This gives ESOP a more accurate method for detecting potential tritium concentrations. Samples are analyzed at the Midlands EQC Region-Aiken Environmental Quality Control (EQC) tritium laboratory on the day of collection. Results from the tritium analysis are used to project tritium activity in the Savannah River. Results from the enhanced program are considered to be unofficial results and are used only for notification purposes.

An additional component of the RSW Project is the Supplemental Surface Water Monitoring Program implemented in 2005. The purpose of this sampling program is to monitor any potential releases of radionuclides. Sample locations are located along Upper Three Runs, Fourmile Branch, and Steel Creek. This monitoring was established for early detection of unplanned releases from SRS source term areas. Samples are collected on Tuesday, prepped the same day, and analyzed for gamma emitting radionuclides the next day as part of a quick scan early detection procedure. These samples are collected as unofficial results for notification purposes only.

In August of 2007, ESOP began collecting ambient grab samples from a location at South Carolina (SC) Highway 125 and Lower Three Runs Creek. This sampling was conducted in response to elevated tritium levels detected in groundwater samples near the Energy Solutions (formerly Chem-Nuclear) facility in Snelling, SC. The purpose of adding this location was to differentiate any potential tritium contributions to Lower Three Runs from Energy Solutions and SRS activities. This sampling location was moved in 2007 to a location (Lower Three Runs Creek and Patterson Mill Road, SV-328) closer to the Energy Solutions source.

Quarterly sampling for iodine-129 (I-129) and technetium-99 (Tc-99) was conducted at the supplemental location on Fourmile Branch due to concerns that these are possible constituents related to effluent from the burial grounds, and modeling projects that this effluent could enter the surface water.

The automatic water samplers located at SV-118 are powered by alternating current. This power source can be interrupted at times due to power outages most often associated with seasonal thunderstorms. Although this interruption of power is infrequent when it occurs, only a partial sample may be collected in the composite sampler. Additionally, the sampling program in the carousel sampler may be halted, resulting in missed samples during a sampling event. All of the other automatic water samplers are powered by solar panels and lead-acid batteries. Any missed composite samples are collected as grab samples.

#### **4.2.0 RESULTS AND DISCUSSION**

##### **4.2.1 SCDHEC Surface Water Data**

All monitoring data are in Appendix A-ESOP Data, and summary statistics are in Section 6.0. All established sampling locations are in Section 5.0, Table 1.

##### Tritium

In 2014, tritium activity was detected at all ambient locations where weekly samples were collected (Section 6.0, Summary Statistics). Average tritium activities at Jackson Boat Landing (SV-2010) and Upper Three Runs Creek at United States Forestry Service (USFS) Rd E-2 (SV-2027) were lower than average tritium activities at the other ambient sample locations. These locations are upstream from SRS impacts and considered background locations. The average detected tritium for these locations was 282 ( $\pm 66$ ) picocuries per liter (pCi/L) for SV-2010 and 276 ( $\pm 26$ ) pCi/L for SV-2027. Fourmile Branch at USFS Rd. 13.2 (SV-2039) and Pen Branch at USFS Rd. 13.2 (SV-2047) continue to yield the highest levels of tritium activity. SV-2039 had an average tritium activity of 34,819 ( $\pm 3,870$ ) pCi/L and SV-2047 had an average tritium activity of 16,912 ( $\pm 6,121$ ) pCi/L. Detected tritium activity at all locations ranged from 229 pCi/L at SV-328 to 44,383 pCi/L at SV-2039. Section 5.0, Figure 1 shows trending for 2010-2014 tritium averages.

Tritium activity in the Savannah River at the creek mouths of the four SRS streams was monitored on a quarterly basis in 2014 (Section 6.0, Summary Statistics). Samples collected at the creek mouth of Fourmile Branch (SV-2015) had the highest average tritium activity (7,684 ( $\pm 8,062$ ) pCi/L) of all creek mouth locations.

While tritium was detected at all public access locations, the results were below the United States Environmental Protection Agency (USEPA) Maximum Contaminant Level (MCL) annual average of 20,000 pCi/L for drinking water.

##### Gamma

As part of a gamma spectroscopy analysis, samples were analyzed for gamma-emitting radionuclides (Section 5.0, Table 2) at the Radiological Environmental Monitoring Division (REMD) Laboratory in Columbia, SC. Cesium-137 has been historically detected in samples collected from Fourmile Branch. This stream was affected by releases from reactor activities, so periodic Cs-137 detections are likely in samples collected from this location (Till, et al. 2001). Cobalt-60 (Co-60) and Americium-241 (Am-241) results were incorporated in the RSW project

report for comparison purposes with DOE-SR data. All Cs-137, Co-60, and Am-241 results from the gamma analysis in 2014 were below their respective Minimum Detectable Activity (MDA).

### Alpha

In 2014, alpha-emitting radionuclides were detected at all of the locations where monthly composite samples were collected (Section 6.0, Summary Statistics). Average detected activity over all locations ranged from a single detection of 0.87 pCi/L at SV-2010 to a single detection of 5.42 pCi/L at SV-2039. SV-324 had detections in six of the 12 samples collected averaging 3.87 ( $\pm 1.19$ ) pCi/L. SV-325 had detections in five of the 12 samples collected averaging 4.43 ( $\pm 0.97$ ) pCi/L. Tims Branch (SV-324) was added as an ambient location in 2014 and is a tributary of Upper Three Runs (SV-325).

Historically, SV-325 yields detections for alpha activity (SCDHEC 2000-2014). Isotopic analysis performed by DOE-SR revealed the source to be natural uranium (SRNS 2011). This may contribute to the common occurrence of alpha detections at this location. The 2014 average alpha activity at SV-325 was below the USEPA MCL for drinking water of 15 pCi/L (USEPA 2002). Beginning in 2009, samples collected at this location exhibited particles of sediment and detritus usually associated with rain events. This increase in turbidity seems to be related to storm events. Samples with high turbidity can have potential interferences during alpha/beta analysis. Alpha particles, and to a lesser extent, beta particles, are attenuated by salts and solids dried onto a planchet (USEPA 2010). This sampling location is monitored for turbidity to ensure it is not a concern in collected samples. Ambient monitoring average annual alpha trends for 2010-2014 are shown in Section 5.0, Figure 2.

The 2014 average alpha activity was below the USEPA MCL for drinking water of 15 pCi/L.

### Beta

Beta-emitting radionuclide activity was detected in two of nine locations where monthly composite samples were collected (Section 6.0, Summary Statistics). The average activity ranged from a single detection of 3.00 pCi/L at SV-2053 to 4.76 ( $\pm 0.92$ ) pCi/L at SV-2039. Fourmile Branch (SV-2039) was primarily affected by releases from the separation areas, so gross beta detections can be expected at this location (Till, et al. 2001). Ambient monitoring average annual beta trends for 2010-2014 are shown in section 5.0, Figure 3. USEPA has established a MCL of 4 millirem per year for beta particle and photon radioactivity from man-made radionuclides in drinking water. The USEPA screening MCL for gross beta-emitting particles for drinking water systems is 50 pCi/L minus natural Potassium-40 (K-40) (USEPA 2002), and all averages were below this limit.

### Iodine-129 and Technetium-99

Iodine-129 and Technetium-99 sampling of the ambient location on Fourmile Branch was monitored on a quarterly basis. There was an I-129 detection in one of the four quarterly

samples above the MDA of 1.52 pCi/L. There was a Tc-99 detection in one of the four quarterly samples of 2.06 pCi/L.

USEPA has established a MCL of 4 millirem per year for beta particle and photon radioactivity from man-made radionuclides in drinking water. Tc-99 would be included under this MCL. The average concentration of Tc-99, which is assumed to yield 4 millirem per year, is 900 pCi/L. The average concentration of I-129, which is assumed to yield 4 millirem per year, is 1 pCi/L. If other radionuclides, emitting beta particles and photon radioactivity are present in addition to Tc-99 and I-129, the sum of the annual dose from all the radionuclides shall not exceed 4 millirem/year (USEPA 2002).

#### **4.2.2 SCDHEC/DOE-SR Data Comparison**

Data from 2014 reported in this project were compared to DOE-SR reported results (Section 5.0, Tables 3, 4, 5). The SCDHEC and DOE-SR colocated sampling sites were Tims Branch at Road C, Upper Three Runs Creek at Road A, Fourmile Branch at USFS Road 13.2, Pen Branch and USFS Road 13.2, Steel Creek at Road A, Lower Three Runs Creek at SRS Road B and at Patterson Mill Road, and the Savannah River at US Highway 301 Bridge. DOE-SR sampled at several other locations along these streams. However, the data comparisons are only for the colocated sample sites.

##### Tritium

DOE-SR reports all values, including values that are negative and ones that are below detection. Therefore, DOE-SR reports an average for all locations derived from detections and non-detection values. For the purpose of this report, the average, median, and standard deviation (SD) for all DOE-SR data were recalculated using detections only for a more accurate comparison. SCDHEC and DOE-SR had detections for tritium at all colocated sample locations (Section 5.0, Table 3). DOE-SR average tritium activities for colocated sites at Tims Branch and Fourmile Branch were within two SD of SCDHEC average tritium activities. The other five colocated sites were within one SD of SCDHEC average tritium activities. SCDHEC and DOE-SR samples indicate that Fourmile Branch (34,819 ( $\pm 3,870$ ) pCi/L and 30,767 ( $\pm 3,333$ ) pCi/L, respectively) and Pen Branch (16,912 ( $\pm 6,121$ ) pCi/L and 14,458 ( $\pm 4,920$ ) pCi/L, respectively) have the highest average tritium activity of all SRS streams. The 2013 SCDHEC and DOE-SR tritium results appear to be consistent with historically reported data values (Section 5.0, Figures 4-9, SCDHEC 2009-2014, SRNS 2010-2015).

##### Gamma

DOE-SR reported two detects of Am-241 averaging (0.025 ( $\pm 0.008$ ) pCi/L (SRNS 2015) at the colocated sample site at Tims Branch. DOE-SR reported a single detection of Am-241 (0.0195 ( $\pm 0.008$ ) pCi/L (SRNS 2015) at the Upper Three Runs Creek colocated sample site. DOE-SR reported another single detection of Am-241 (0.019 ( $\pm 0.006$ ) pCi/L (SRNS 2015) at the Fourmile Branch colocated sample site. DOE-SR reported a single detection of Am-241 (0.009 ( $\pm 0.004$ ) pCi/L (SRNS 2015) at the Steel Creek colocated sample site. SCDHEC had no gamma detected above the MDA in 2014.

### Alpha

DOE-SR and SCDHEC detected gross alpha activity at all of the colocated sampling locations (Section 5.0, Table 4). SCDHEC and DOE-SR samples collected from Upper Three Runs Creek exhibited the highest gross alpha average activity (4.43 ( $\pm 0.97$ ) pCi/L and 14.06 ( $\pm 16.08$ ) pCi/L, respectively) (SRNS 2015). SCDHEC and DOE-SR samples collected from Tims Branch at Road C exhibited the highest single gross alpha concentration (4.96 pCi/L and 88.60 pCi/L, respectively) (SRNS 2015).

### Beta

SCDHEC detected gross beta activity at two of the seven colocated sampling locations while DOE-SR detected activity at all seven colocated locations (Section 5.0, Table 5). SCDHEC only detected gross beta activity at Fourmile Branch and Lower Three Runs Creek. SCDHEC samples collected from Fourmile Branch exhibited the highest gross beta average activity (4.76 ( $\pm 0.92$ ) pCi/L). DOE-SR samples collected from Tims Branch exhibited the highest gross beta average activity 11.33 ( $\pm 14.84$ ) pCi/L (SRNS 2015).

### Iodine-129 and Technetium-99

SCDHEC and DOE-SR do not have a colocated sampling site for Iodine-129 and Technetium-99. Therefore, these analytes were not compared.

## **4.3.0 CONCLUSIONS AND RECOMMENDATIONS**

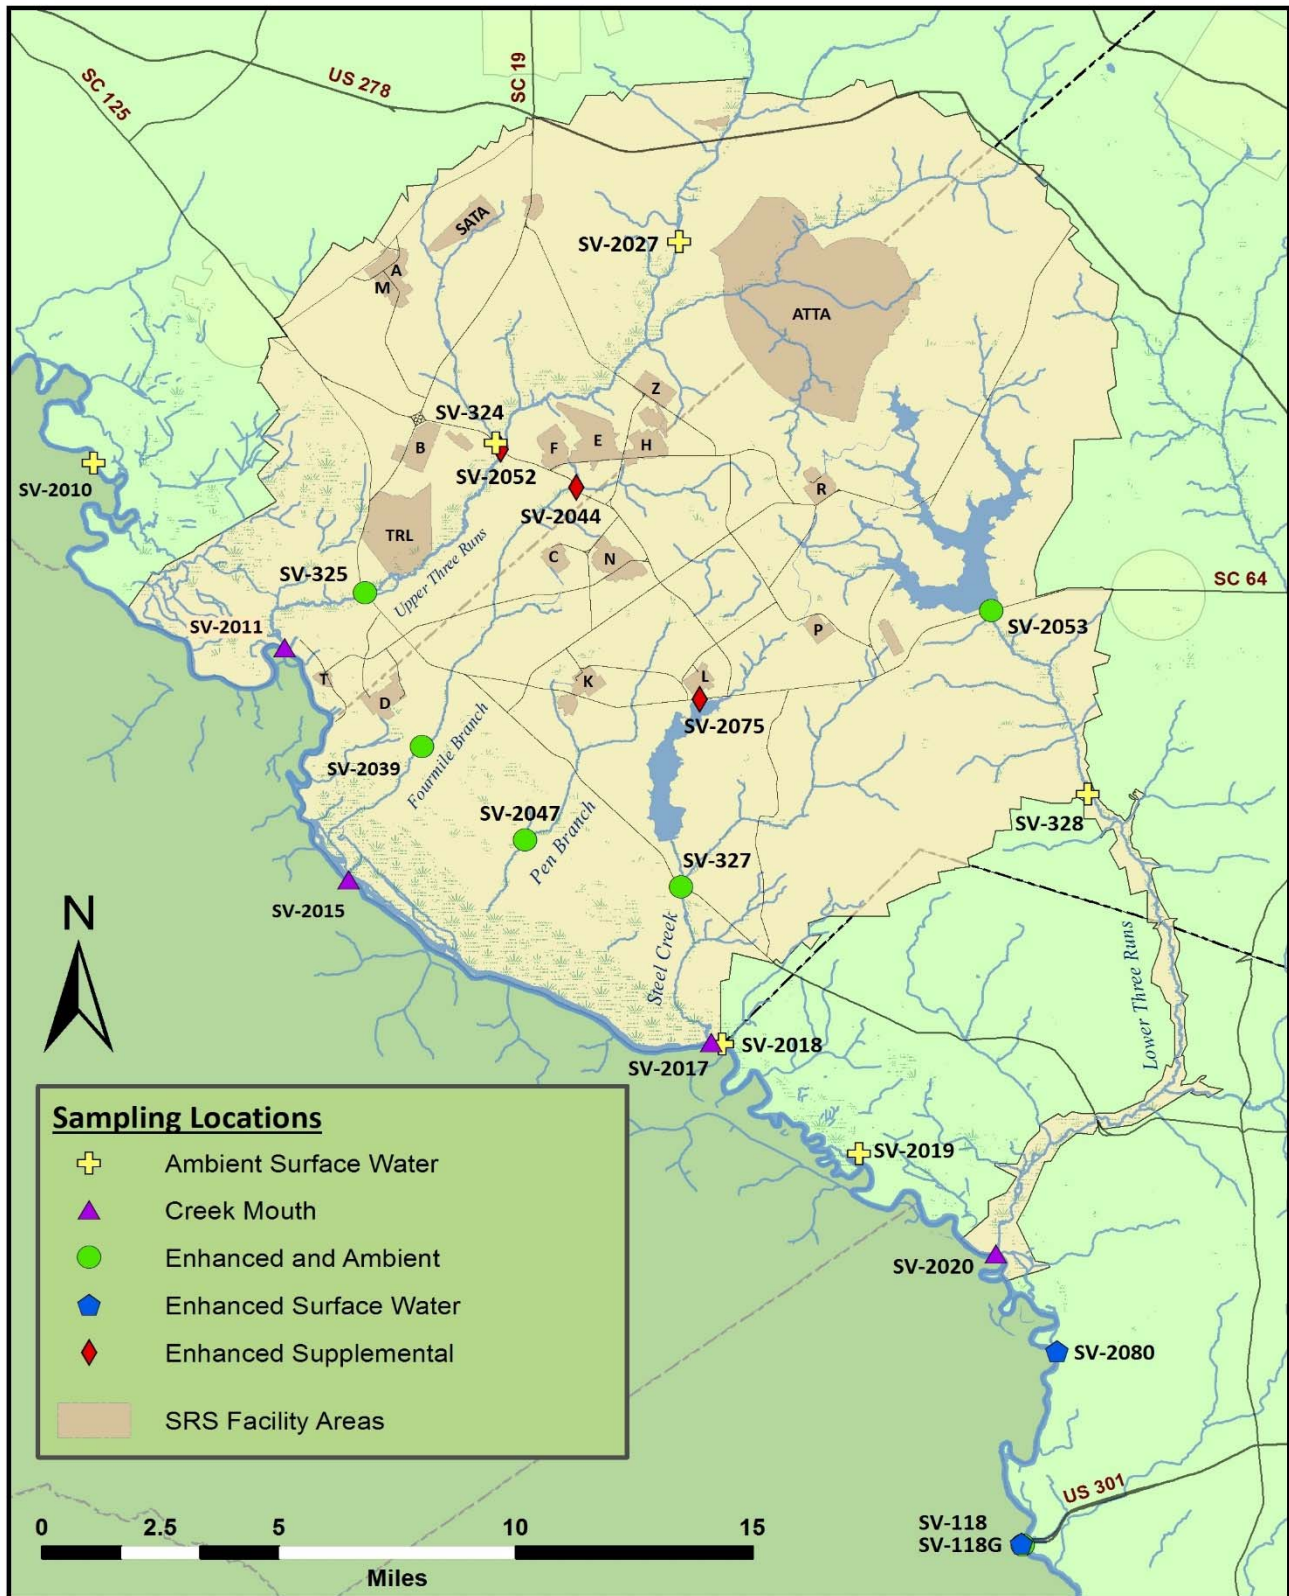

While tritium was detected at all public access locations, the results were below the USEPA MCL annual average of 20,000 pCi/L for drinking water. (USEPA 2002a).

Differences in average values between SCDHEC and DOE-SR could be attributed, in part, to the nature of the water medium and the specific point and time when the sample was collected.

The ESOP RSW project will continue to independently collect and analyze surface water on and adjacent to SRS. This monitoring effort will provide an improved understanding of radionuclide levels in SRS surface waters and valuable information relative to human health exposure pathways. The RSW project will periodically evaluate modifications of the monitoring activities to better accomplish the project's goals and objectives. Further refinement of the RSW project may result in additional sampling locations being incorporated into the ambient or enhanced monitoring regimes. Monitoring will continue as long as there are activities at SRS that create the potential for contamination entering the environment. Continued monitoring will provide an improved understanding of radionuclide activity in SRS surface waters and the Savannah River, which will provide valuable information to human health exposure pathways. This comparison of data results allows for independent data evaluation of DOE-SR monitoring activities.

4.4.0 MAP

# Radiological Surface Water Sampling Locations

4.5.0 TABLES AND FIGURES

Table 1. 2014 Surface Water Sampling Locations and Frequency

Ambient Monitoring Locations

ID	Location	Rationale	Frequency
SV-2010	Savannah River at RM 170.5 (Jackson Boat Landing)	Accessible to public; above all SRS operations; Near Jackson population center; Up river control; River monitoring	Weekly tritium; Monthly Alpha, Beta, and Gamma composite
SV-325	Upper Three Runs Creek at SC 125 (SRS Road A)	Within SRS perimeter; Below SRS operations areas; Tributary monitoring	Weekly tritium; Monthly Alpha, Beta, and Gamma composite
SV-2039	Fourmile Branch at Road A-13.2	Within SRS perimeter; Below SRS operations areas; Tributary monitoring	Weekly tritium; Monthly Alpha, Beta, and Gamma composite
SV-2047	Pen Branch at Road A-13.2	Within SRS perimeter; Below SRS operations areas; Tributary monitoring	Weekly tritium; Monthly Alpha, Beta, and Gamma composite
SV-327	Steel Creek at SC 125 (SRS Road A)	Within SRS perimeter; Below SRS operations areas; Tributary monitoring	Weekly tritium; Monthly Alpha, Beta, and Gamma composite
SV-2018	Savannah River at RM 141 (Steel Creek Boat Landing)	Accessible to the public; Adjacent to SRS perimeter Below SRS operations; River monitoring	Weekly tritium; Monthly Alpha, Beta, and Gamma composite
SV-2019	Savannah River at RM 134.5 (Little Hell Boat Landing)	Accessible to the public; Below SRS operations and tributaries; River monitoring	Weekly tritium grab
SV-2080	Savannah River at RM 125 (Johnson's Boat Landing)	Accessible to the public; Below SRS operations and tributaries; River monitoring	Tri-weekly tritium grab
SV-118	Savannah River at RM 118.8 (Hwy 301 Bridge)	Accessible to the public; Below SRS operations and tributaries; River monitoring	Weekly tritium; Monthly Alpha, Beta, and Gamma composite
SV-328	Lower Three Runs Creek at Patterson Mill Road	Within SRS perimeter; Below SRS operations and Par Pond; Tributary monitoring	Weekly tritium grab
SV-2053	Lower Three Runs Creek at Road B	Within SRS perimeter; Below SRS operations and Par Pond; Tributary monitoring	Weekly tritium; Monthly Alpha, Beta, and Gamma composite
SV-2027	Upper Three Runs Creek at SRS Road 2-1	Within SRS perimeter; Upstream from SRS operations; Upstream control; Tributary monitoring	Weekly tritium grab

Notes:

1. ID is Sampling Location Identification Code Number
2. RM is River Mile
3. Tri-Weekly Enhanced sample data is not used for reporting purposes only for early detection

and Environmental Control

### **5.1.0 PROJECT SUMMARY**

The streams located on the Savannah River Site (SRS) receive a wide variety of permitted point source discharges and non-point source run-off from on-site facilities and operations. These discharges specifically include, but are not limited to, industrial storm water, utility water, treated industrial and sanitary wastewater, and run-off from land disturbing activities. Data from SRS Environmental Reports and South Carolina Department of Health and Environmental Control's (SCDHEC) Environmental Surveillance and Oversight Program (ESOP) is used to monitor the ambient water quality of streams on SRS.

SCDHEC assessed the surface water quality for nonradiological parameters in 2014 at SRS by sampling the on-site streams for inorganic and organic contaminants. The streams on SRS are tributaries to the Savannah River and are classified as Freshwater (FW) by SCDHEC's Bureau of Water (SCDHEC 2008a). As an indication of possible water quality issues, SCDHEC data was compared to the FW standard guidelines in SCDHEC's Water Classifications and Standards, Regulation 61-68. These guidelines give numeric criteria for specific parameters and narrative criteria that indicate conditions of biological integrity and water quality for aquatic life and human health (SCDHEC 2008b). The fact that a stream does not meet the specified numeric standards for a particular parameter does not mean the stream is polluted or of poor quality. Natural conditions can cause streams to exceed the standards. Where appropriate, SCDHEC results were also compared to the Savannah River watershed data collected by SCDHEC's Bureau of Water from 2008 through 2012 (SCDHEC 2013). This data includes averages and data ranges for all streams in the entire Savannah River Basin.

Nine SCDHEC sample locations were strategically chosen to monitor ambient surface water conditions and detect the nonradiological impact from the Department of Energy – Savannah River (DOE-SR) operations. See Section 4.0 for a map of SCDHEC sample locations. The stream sample locations were selected based on accessibility and their proximity upstream and downstream of DOE-SR operations before flowing into the publicly accessible Savannah River (Section 5.0, Table 1). Six of the SCDHEC sample locations were co-located with DOE-SR sample locations to provide data comparisons (Section 5, Table 3).

Streams were tested for the following parameters on a monthly interval: pH, dissolved oxygen (DO), temperature, alkalinity, turbidity, biochemical oxygen demand (BOD), total suspended solids (TSS), E. coli, total Kjeldahl nitrogen (TKN), ammonia, nitrate/nitrite, total phosphorous, cadmium, chromium, copper, iron, lead, manganese, mercury, nickel, and zinc. Volatile organic compounds (VOCs), pesticides, and polychlorinated biphenyls (PCBs) were sampled biannually. These are standard parameters used to indicate water quality in freshwater streams throughout South Carolina (SCDHEC 2011a). In all, 3700 individual analyses were performed with 134 of these individual parameters exceeding South Carolina or United States Environmental Protection Agency (USEPA) standards or other recommended guidelines. Data from SCDHEC surface water locations were compared to DOE-SR data where sample points

were co-located (SCDHEC 2012). All surface water data can be found in Appendix A-ESOP Data, and surface water statistical analyses can be found in Section 6.0.

## **5.2.0 RESULTS AND DISCUSSION**

### **5.2.1 pH Results**

Many chemical and biological processes in surface waters can be affected by pH, a measurement that indicates the alkalinity or acidity of a substance (USEPA 1997). The streams encountered at SRS are typical of southeastern streams characterized as blackwater. A blackwater stream is a stream with a deep, slow moving channel that flows through forested swamps and wetlands. Decaying vegetation in the water results in the leaching of tannins from the vegetation resulting in transparent, acidic water that is darkly stained, resembling tea or coffee. Low pH is typical for blackwater streams such as those sampled at SRS (USGS 2000).

The pH standard for all South Carolina freshwater streams is between 6.0 and 8.5 standard units (su), although lower pH is typical for blackwater streams (SCDHEC 2008b). SCDHEC personnel measured and recorded the pH at each sample location during the sampling event. There were nine individual measurements at four locations that were outside of the pH standard, including locations downstream and upstream of SRS operations (Section 6.0, Summary Statistics, Appendix A-ESOP Data). None of these locations had yearly averages outside of the standard. These are typical results for blackwater streams. The Savannah River Basin's pH averaged 6.69, and ranged from 4.6 to 8.61 (SCDHEC 2013). All SCDHEC sample measurements were within this range. See Section 5.0, Figure 1 for a comparison of SCDHEC and DOE-SR data for co-located samples; there were no significant differences (SRNS 2015).

### **5.2.2 DO and BOD Results**

Oxygen is cycled through the environment and is both produced and consumed in streams. The amount of oxygen in its dissolved form in water is the dissolved oxygen (DO). The BOD is the amount of oxygen consumed by microorganisms in stream water. Water quality is diminished when the BOD is high, which depletes the oxygen in the water. Low DO means less oxygen to sustain higher forms of aquatic life (USEPA 1997).

Dissolved oxygen was measured and recorded in the field as part of each SCDHEC sampling event, and samples were collected for BOD analysis. The South Carolina freshwater standard for DO is a daily average no less than 5.0 milligrams per liter (mg/L) with a minimum of 4.0 mg/L (SCDHEC 2008b). The monthly sampling frequency employed by SCDHEC is insufficient for strict interpretation related to the standards. The SCDHEC grab sample method is considered to be representative and provides an indication of water quality relative to DO. All individual samples and yearly averages met the DO standard in 2014 (Section 6.0, Summary Statistics, Appendix A-ESOP Data). The SCDHEC Bureau of Water Savannah River Basin's DO averaged 8.83 mg/L, and ranged from 0.66 mg/L to 15.4 mg/L (SCDHEC 2013). All SCDHEC sample

measurements were within this range. See Section 5.0, Figure 2 for a DO comparison of SCDHEC and DOE-SR data for co-located samples; there were no significant differences (SRNS 2015).

There are no numeric criteria in the South Carolina freshwater standards for a maximum BOD level; however, all 2014 SCDHEC samples were near or below the lower limit of detection (LLD) of 2.0 mg/L (Section 6.0, Summary Statistics, Appendix A-ESOP Data). These results show no indication of water quality issues relative to BOD in SRS streams. The Savannah River Basin results ranged from <LLD to 6.4 mg/L (SCDHEC 2013). All SCDHEC samples results were within this range. DOE-SR did not collect BOD samples in 2014; therefore, no comparison was made for BOD.

### **5.2.3 Temperature Results**

Temperature can affect biological and chemical processes in a stream. All aquatic organisms can be negatively impacted by temperature that varies from the naturally occurring range (USEPA 1997). The South Carolina freshwater standards state the temperature of free flowing freshwater shall not be increased more than 2.8°C above natural temperature conditions and shall not exceed a maximum of 32.2°C (SCDHEC 2008b).

SCDHEC field personnel measured and recorded the temperature during each sampling event in 2014. SCDHEC did not collect temperature data above and below every possible point of impact; therefore, the results were insufficient for strict interpretation related to the standard. However, SCDHEC data showed that the stream temperatures at each sampling event were comparable to each other, including samples representative of natural conditions that were upstream of most SRS operations (Section 6.0, Summary Statistics, Appendix A-ESOP Data). Overall the results do not indicate any water quality issues relative to temperature. No comparisons were made between SCDHEC results and the Savannah River watershed or DOE-SR results due to the high variability in temperature dependent on the day and the time of day samples were collected.

### **5.2.4 Alkalinity Results**

Alkalinity is important for aquatic life in freshwater systems because it buffers pH changes that occur naturally or as a result of anthropogenic sources. Components of alkalinity, such as carbonate and bicarbonate, will incorporate some toxic heavy metals and reduce their toxicity (USEPA 1997). There are no numeric criteria in the South Carolina freshwater standards for alkalinity. However, the National Technical Advisory Committee recommends a minimum alkalinity of 20 mg/L and that natural alkalinity not be reduced by more than 25 percent (National Academy of Sciences (NAS) 1974). Waters having insufficient alkalinity due to natural conditions do not have to be supplemented with artificially added materials to increase the alkalinity. Alkalinity resulting from naturally occurring materials, such as carbonate and bicarbonate, is not considered a health hazard in drinking water supplies. Naturally occurring maximum levels up to approximately 400 mg/L, as calcium carbonate, are not considered a problem to human health (NAS 1974).

SCDHEC sampled each location monthly in 2014 for alkalinity. Seventy-four individual samples at eight locations were below the recommended minimum level (Section 6.0, Summary Statistics, Appendix A-ESOP Data). Six of these locations had yearly averages below the recommended level: NWSV-324 (5.3 ( $\pm 1.9$ ) mg/L), NWSV-325 (3.9 ( $\pm 0.60$ ) mg/L), NWSV-2027 (0.79 ( $\pm 0.54$ ) mg/L), NWSV-2039 (12.11 ( $\pm 1.8$ ) mg/L), NWSV-2055 (16.38 ( $\pm 4.3$ ) mg/L), and NWSV-2061 (5.1 ( $\pm 2.0$ ) mg/L). The low alkalinity, as related to pH, in SRS streams may be due to the presence of naturally low buffering compounds in the streams. These conditions were consistent even in the samples upstream of most SRS operations, represented by NWSV-2027 and NWSV-2061. The Savannah River Basin's alkalinity averaged 24.69 mg/L, and ranged from 1 mg/L to 160 mg/L (SCDHEC 2013). All SCDHEC sample results were within this range. DOE-SR did not sample for alkalinity in 2014; therefore, no comparison was made.

### **5.2.5 Turbidity and TSS Results**

Turbidity is a measure of water clarity or the amount of light that passes through the water. The freshwater quality standard for turbidity in South Carolina streams is not to exceed 50 nephelometric turbidity units (NTU) provided existing uses are maintained (SCDHEC 2008b). All SCDHEC monitored streams were below the standard for turbidity in 2014 (Section 6.0, Summary Statistics, Appendix A-ESOP Data). The SCDHEC sample results ranged from 0.8 mg/L to 13 mg/L. This is comparable to the Savannah River Basin's turbidity ranging from 0.8 mg/L to 320 mg/L (SCDHEC 2013). All SCDHEC sample results were within this range. DOE-SR did not sample for turbidity in 2014; therefore, no comparison was made.

Turbidity is directly affected by the water's TSS, which refers to the amount of material suspended in the water (USEPA 1997). There is no freshwater quality standard for TSS. The SCDHEC sample results ranged from 1.0 mg/L to 12 mg/L (Section 6.0, Summary Statistics, Appendix A-ESOP Data). This is comparable to the Savannah River Basin's TSS ranging from 1 mg/L to 43 mg/L (SCDHEC 2013). See Section 5.0, Figure 3 for a TSS comparison of SCDHEC and DOE-SR data for co-located samples; there were no significant differences (SRNS 2015).

### **5.2.6 E. coli Results**

In 2013, SCDHEC switched from sampling for fecal coliform to *E. coli*. This is a species of coliform bacteria, only found in human and other mammal waste, and a good indicator of human health risk. The South Carolina freshwater *E. coli* standard is a daily maximum of 349 Most Probable Number (MPN) per 100ml. SCDHEC field personnel collected monthly surface water samples for *E. coli* analysis at each location in 2014. There were 27 individual samples at all nine locations that exceeded 349 MPN per 100ml. Three locations also had yearly averages above the standard; NWSV-327 (373 ( $\pm 656$ ) MPN), NWSV-328 (412 ( $\pm 653$ ) MPN), and NWSV-2055 (533 ( $\pm 614$ ) MPN). The SCDHEC sample results ranged from 3.1 MPN to >2419.6 MPN. This is comparable to the Savannah River Basin's *E. coli* ranging from 4 MPN to 6931.6 MPN (SCDHEC 2013).

All SCDHEC sample results were consistent with this range. DOE-SR did not collect samples for E. coli in 2014; therefore, no comparison was made.

### **5.2.7 Nutrient Results**

Phosphorous and nitrogen are essential nutrients for the plants and animals that make up the aquatic food web; however, in excess they can cause significant water quality problems. Phosphorous and nitrogen cycle through the environment in a variety of forms, and can indirectly impact DO and other water quality indicators (USEPA 1997). In 2014, SCDHEC sampled for total phosphorous and various forms of nitrogen, including nitrite/nitrate, TKN, and ammonia. There are no numeric criteria in the South Carolina freshwater standard for any of these parameters.

SCDHEC uses the most conservative of the federally established drinking water standards for nitrate/nitrite levels to indicate ambient water quality in freshwater streams for nutrients. The USEPA drinking water standards for nitrate/nitrite levels are 10 mg/L and 1 mg/L, respectively, and are designed to protect the public from consumption (USEPA 2009a). To provide a conservative approach, SCDHEC uses the maximum of 1 mg/L as an indication of possible water quality issues. Three locations had one sample each above 1mg/L; NWSV-324 (1.6 mg/L in February), NWSV-2027 (1.1 mg/L in August), and NWSV-2039 (1.2 mg/L in January) (Appendix A-ESOP Data). Fourmile Branch (NWSV-2039) typically has nitrogen levels higher than other SRS streams due to an upstream wastewater treatment plant or groundwater beneath F-Area and H-Area seepage basins outcropping into the creek (RAC 1999). However, no location had a 2014 yearly average that exceeded the drinking water standard (Section 6.0, Summary Statistics, Appendix A-ESOP Data).

The SCDHEC results for total phosphorous ranged from <LLD to 0.17 mg/L. The Savannah River Basin results ranged from <LLD to 2.7 mg/L. All SCDHEC total phosphorous results were within this range.

The SCDHEC nitrate/nitrite results ranged from <LLD to 1.6 mg/L. The Savannah River Basin results ranged from <LLD to 7.6 mg/L. All SCDHEC nitrate/nitrite results were within this range.

The SCDHEC TKN results ranged from <LLD to 0.7mg/L. The Savannah River Basin results ranged from <LLD to 2.4 mg/L. All SCDHEC TKN results were within this range.

The SCDHEC ammonia results ranged from <LLD to 0.15 mg/L. The Savannah River Basin results ranged from <LLD to 0.39 mg/L. All SCDHEC ammonia results were within this range.

Overall the nutrient levels on SRS are similar to the levels found throughout the Savannah River Basin. DOE-SR did not sample for TKN or ammonia in 2014; therefore, no comparison was made. See Section 5.0, Figure 4 and Figure 5 for a comparison of

SCDHEC and DOE-SR data from co-located samples for total phosphorous and nitrate/nitrite, respectively. There were no significant differences (SRNS 2015).

### **5.2.8 Metals Results**

Most metals are considered to be pollutants, including some that are toxic or known carcinogens. In 2014, SCDHEC personnel collected monthly samples at each sample location for the following metals: cadmium, chromium, copper, iron, lead, manganese, mercury, nickel, and zinc. All metals data is included in Appendix A-ESOP Data. Yearly averages were calculated for all metals; however, many of these averages are based on a single detection (Section 6.0, Summary Statistics, Appendix A-SCDHEC Data). Due to the potential health effects of some metals, a yearly average, even if based on a single detection that exceeds the freshwater standards, may indicate a water quality issue. All of these metals (except iron and manganese) have numeric criteria for the protection of human health and aquatic life in the South Carolina freshwater quality standards.

Iron and manganese are naturally occurring metals. Iron has a recommended USEPA limit in freshwater streams of 1 mg/L (USEPA 2008). Seventeen individual SCDHEC samples at four locations had iron above this recommended level. One location had a yearly average above the recommended level, NWSV-324 (3.0 ( $\pm$ 1.0) mg/L). The SCDHEC sampling location NWSV-324 and DOE-SR TB-5 are located on Tim's Branch which has several ground water seeps that contribute to its relatively low flow. It is likely that the elevated iron measured at this location is influenced by naturally occurring processes. DOE-SR results for co-located samples indicated the same location, in addition to NWSV-2039, had yearly averages at or above the recommended level for iron (SRNS 2015).

The SCDHEC sample results for iron ranged from <LLD to 4.4 mg/L. The Savannah River Basin's iron levels ranged from 0.03 mg/L to 7.9 mg/L (SCDHEC 2013). All SCDHEC sample results were within this range. The EPA recommended limit for iron is 1 mg/L. NWSV-2039 was the only location average above this limit for both organizations. DOE-SR also detected iron in each co-located sample location but with two locations above the recommended limit.

The SCDHEC manganese sample results ranged from <LLD mg/L to 0.33 mg/L. The Savannah River Basin's manganese levels ranged from 0.01 mg/L to 5.4 mg/L (SCDHEC 2013). All SCDHEC sample results were within this range. SCDHEC and DOE-SR detected manganese in each of the co-located sample locations. There is no standard for this analyte. See Section 5.0, Figure 6 and Figure 7 for an iron and manganese comparison of SCDHEC and DOE-SR data for co-located samples; there were no significant differences (SRNS 2015).

The freshwater quality standard for cadmium in South Carolina streams is not to exceed 0.00010 mg/L (SCDHEC 2008b). One individual SCDHEC sample had a cadmium level above the standard, NWSV-324 (0.0003 mg/L). Because of this one detection, this location's yearly average is also above the standard. DOE-SR detected cadmium above

the standard at all six of the co-located sample locations in 2014. (SRNS 2015). See Section 5.0, Figure 8 for a comparison of SCDHEC and DOE-SR cadmium data.

The freshwater quality standards for chromium, copper, and nickel in South Carolina streams are not to exceed 0.011 mg/L, 0.0029 mg/L and 0.016 mg/L, respectively (SCDHEC 2008b). There were no SCDHEC detections of chromium in 2014. DOE-SR detected chromium in all six co-located sample locations with no results above the standard. SCDHEC did not detect copper in 2014. DOE-SR detected copper at or above the standard in at least one sample from four of six co-located sample locations. However, there were only three of six DOE-SR locations where the yearly average was above the standard. It should be noted that some of the averages were derived from one or two detections. The DOE-SR copper detections were found at levels below SCDHEC LLD. SCDHEC did not detect nickel in 2014. DOE-SR detected nickel in each of the co-located sample locations, with one location (SC-4) average over the standard. The DOE-SR nickel detections were found at levels below SCDHEC LLD.

The freshwater quality standard for lead in South Carolina streams is not to exceed 0.00054 mg/L (SCDHEC 2008b). Due to laboratory limitations, SCDHEC has an LLD higher than the standard at 0.0020 mg/L; therefore, any detection of lead is over the standard. There were no SCDHEC detections in 2014. DOE-SR detected lead above the standard at four of the co-located sample locations (SRNS 2015). The DOE-SR lead detections were found at levels below SCDHEC LLD.

The freshwater quality standard for mercury in South Carolina streams is not to exceed 0.00091 mg/L (SCDHEC 2008b). Mercury was not detected above the LLD of 0.00020 mg/L in any of the SCDHEC samples in 2014; therefore, all SCDHEC monitored streams met the standard for this parameter. DOE-SR has a mercury detection limit of 0.00002 mg/L. DOE-SR detected mercury at levels below the SCDHEC LLD in several of the co-located samples. None of these detections were over the freshwater quality standard (SRNS 2015).

The freshwater quality standard for zinc in South Carolina streams is not to exceed 0.037 mg/L (SCDHEC 2008b). SCDHEC had one sample over the standard in 2014, NWSV-2039 (0.039 mg/L). DOE-SR detected zinc above the standard in at least one sample from one co-located sample location; however, no yearly average was above the standard. See Section 5.0, Figure 9 for a zinc comparison of SCDHEC and DOE-SR yearly averages for co-located samples, there were no significant differences (SRNS 2015).

### **5.2.9 VOCs, PCBs and Pesticide Results**

Most VOCs, PCBs, and pesticides are considered to be pollutants including some that are toxic. Most have numeric criteria for the protection of human health and aquatic life in the South Carolina freshwater quality standards. SCDHEC field personnel collected surface water samples for VOC, PCB, and pesticides at each location biannually. SCDHEC sampled for 59 individual VOC, PCB, and pesticide parameters at each location during the Spring and Fall of 2014. All data is included in Appendix A-ESOP Data. There were no SCDHEC detections of VOC, PCB, or pesticide contaminants in

2014. DOE-SR did not detect any other VOC, PCB, or pesticide parameters in 2014 other than a single detection of endosulfan sulfate at FM-6 (NWSV-2039) (SRNS 2015).

### **5.2.10 SCDHEC and DOE-SR Data Comparison**

Six of the nine SCDHEC sampling locations were co-located with DOE-SR sampling locations: NWSV-324, NWSV-325, NWSV-327, NWSV-328, NWSV-2039, and NWSV-2047 (SRNS 2015). Section 5.0, Table 1 defines the geographic locations of the SCDHEC sampling locations and Section 5.0, Table 2 defines the sampling schedule for SCDHEC. Section 5.0, Table 3 defines the geographic locations of all the DOE-SR sampling locations. Comparisons were made for each parameter individually in the text above. Some comparisons include graphs located in Section 5 that show data from the six co-located samples to determine if there were any significant statistical differences in the following parameters: pH (Figure 1), DO (Figure 2), TSS (Figure 3), total phosphorous (Figure 4), nitrate/nitrite (Figure 5), iron (Figure 6), manganese (Figure 7), cadmium (Figure 8), and zinc (Figure 9). Small discrepancies in data between DOE-SR and SCDHEC may be attributed to differences in sample collection date, sample collection time, sample preservation, and lab analysis. Differences in statistical calculations, such as the yearly averages, may also attribute to dissimilarities. All data less than the LLD were left out of SCDHEC statistical calculations due to the lack of numeric data.

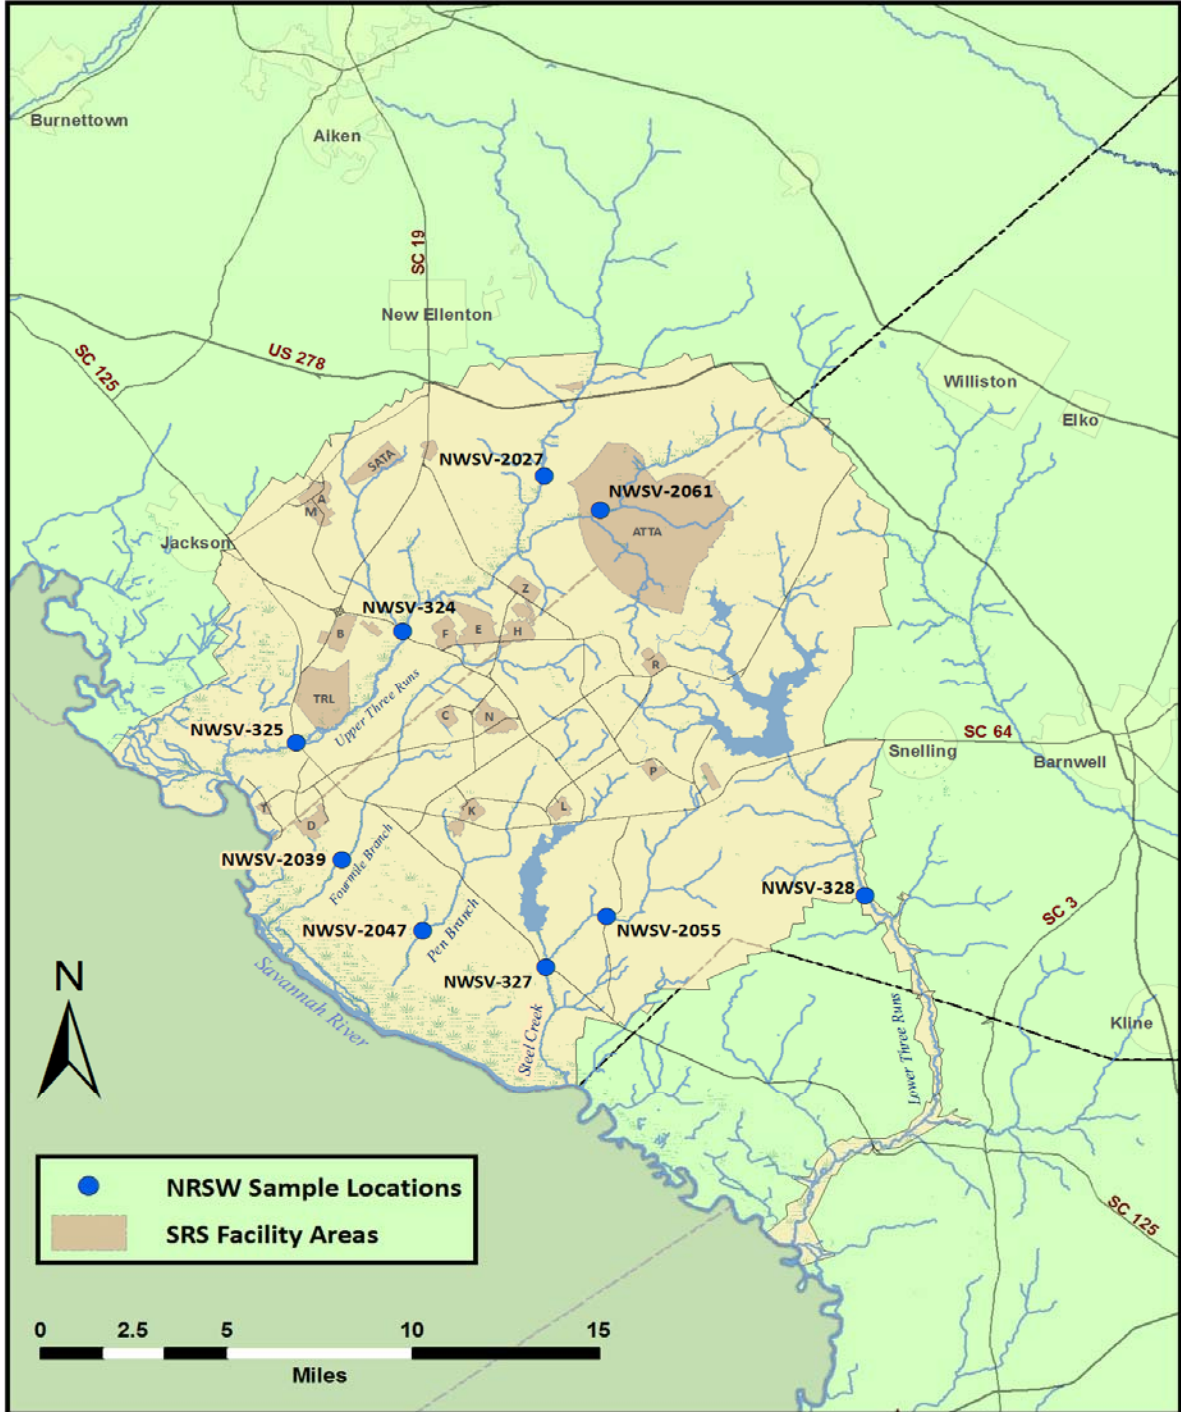

### **5.3.0 CONCLUSIONS/RECOMMENDATIONS**

The parameters identified that were above or below USEPA or SCDHEC standards or recommended levels for particular streams will continue to be monitored to establish trends that may warrant further investigation. Overall, the nonradiological water quality on the SRS in 2014 compared favorably with the South Carolina Freshwaters Standard or other recommendations for the parameters and locations monitored in this study. The 2014 SCDHEC results for most parameters were similar to the SCDHEC's Bureau of Water data for the Savannah River watershed as a whole. SCDHEC will continue to sample on a monthly and biannual basis for routine parameters. SCDHEC will continue to evaluate water quality based on the independent nonradiological monitoring and surveillance of SRS surface water. Monitoring is required due to continued land disturbance from clean-up activities, new facility construction, logging, and new missions. The locations, number of samples, sample frequencies, and monitoring parameters are reviewed annually and modified as needed to maximize available resources and address SRS mission changes.

5.4.0 MAP

# Nonradiological Surface Water Sampling Locations

5.5.0 TABLES AND FIGURES

Table 1. SCDHEC Surface Water Sample Locations

Sample Location	Location Description	Location Rationale
NWSV-2027	Upper Three Runs at Road 2-1	Upstream of most SRS Operations
NWSV-2061	Tinker Creek at Road 2-1	Upstream of most SRS Operations
NWSV-324	Tims Branch at Road C	Downstream from M- & A-Areas
NWSV-325	Upper Three Runs at Road A	Downstream from F-Area
NWSV-2055	Meyers Branch at Road 9	Downstream from P-Area
NWSV-2039	Fourmile Branch at Road A-13.2	Downstream from F- and H-Areas
NWSV-2047	Pen Branch at Road A-13.2	Downstream from K-Area
NWSV-327	Steel Creek at Road A	Downstream from L-Lake
NWSV-328	Lower Three Runs at Patterson Mill Road	Downstream from Par Pond

Table 2. Water Quality Parameter Analyses for SCDHEC

Laboratory	Frequency	Parameter
SCDHEC Lab Aiken, SC	Monthly	Turbidity, BOD, E. Coli, and TSS
SCDHEC Lab Columbia, SC	Monthly	Alkalinity, Ammonia, Nutrients, Mercury, and Metals
	Semi-annually	VOCs, Pesticides, and PCBs
Field	Monthly	Temperature, pH, and DO

Table 3. DOE-SR Surface Water Sample Locations

SRS Stream Locations	Savannah River Locations
Tinker Creek near Northeast Site Boundary	River Mile 160
Tims Branch at Road C*	River Mile 150.4
Upper Three Runs at Road 1-A	River Mile 141.5
Upper Three Runs at Road A*	River Mile 129.1
Beaver Dam Creek at D-Area	River Mile 118.8
Four Mile Creek at Road E	
Four Mile Creek at Road C	
Four Mile Creek adjacent to D-Area*	
Pen Branch at Road A-13.2*	
Steel Creek at Road A*	
Lower Three Runs at Patterson Mill Road*

South Carolina Department of Health  
and Environmental Control

### 6.1.0 PROJECT SUMMARY

The accumulation of radiological and nonradiological contaminants in sediment can have direct impacts on aquatic organisms that can result in human exposure. Point source and nonpoint source pollutants impact water bodies through direct discharge, atmospheric fallout, or through runoff. These accumulated contaminants may become resuspended in streams and rivers. Contaminants dispersed downstream potentially impact drinking water supplies and fish consumed by the public. The high transportation of sediments is a complicated issue; stream flow changes can redistribute contaminants or bury them as part of the natural sedimentation process. Patterns of sediment contamination are strongly affected by hydrologic factors and the physical and chemical characterization of the sediment (USEPA 1987).

Savannah River Site (SRS) streams receive surface water runoff and water from permitted discharges. Stormwater basins may receive runoff and atmospheric fallout from diffuse and fugitive sources (USDOE 1995). Cesium-137 (Cs-137) contamination occurs along the entire length of Lower Three Runs, Steel Creek on SRS, and the private property of Creek Plantation. This contamination occurred due to accidental releases of nuclear material from past operations.

Although DOE-SR conducted sediment remediation along Lower Three Runs creek in 2012, Lower Three Runs and Steel Creek watersheds still represent a possible pathway for release of contamination from SRS activities to both on-site and off-site receptors in the environment (WSRC 2002). Flooding and dam releases from Par Pond and L-Lake scour creek bottoms that may result in the resuspension of contaminated sediments. SRS is within the Savannah River watershed, with five major streams feeding into the Savannah River. Dispersal of any contaminants from these streams has the potential to impact the publicly accessible Savannah River.

The South Carolina Department of Health and Environmental Control (SCDHEC) Environmental Surveillance and Oversight Program (ESOP) provides independent evaluation of the Department of Energy-Savannah River (DOE-SR) environmental monitoring programs. ESOP personnel independently evaluated sediment samples for radionuclide and nonradionuclide contaminant concentrations in SRS streams, SRS stormwater basins, creek mouths along the boundary of SRS, the Savannah River, and publicly accessible sites in the SRS vicinity. Background locations are sampled to compare ambient levels of radionuclides from offsite locations to determine potential impacts due to SRS operations. Sediment samples on SRS are routinely split with DOE-SR in order to compare results.

Ten metals were analyzed in creek mouth and boat landing samples collected in 2014. A complete list of all nonradiological analytes can be found in Section 5.0, Table 4.

The ESOP ambient sediment monitoring project changed in 2007 to include more background sediments (those greater than 50 miles from the SRS center point) within the boundaries of the state of South Carolina. This sampling program was implemented to allow statistical comparisons of the SRS perimeter and South Carolina background contaminant levels in sediment.

ESOP sampled 15 locations at SRS in 2014 with the cooperation of DOE-SR personnel. SRS sediment sampling locations are illustrated in Section 4.0, Map. Split samples were collected from seven stream locations on SRS, and from three SRS stormwater basins. These locations are not publicly accessible. Creek mouth sediment samples at five publicly accessible locations along the Savannah River were also co-sampled (Section 5.0, Table 1). The Pen Branch creek mouth was not sampled because it flows into a swamp area where there is no creek mouth access. Ten sediment samples were also collected from publicly accessible boat landings. In addition, ESOP independently sampled six random background sediments locations.

All SRS split samples were analyzed for gross alpha, gross beta, and gamma. Additionally, SRS creek mouths, and publicly accessible boat landings were analyzed for metals. All samples collected from random background locations were analyzed for gross alpha, gross beta, and gamma radionuclides. Additionally, isotopic analysis was conducted on three SRS accessible creek mouths. Evaluation of radiological and nonradiological contaminants in sediment is necessary to detect any impact from DOE-SR operations beyond historically impacted areas. Radionuclide detections in sediment are typically the result of accumulation over many years and do not represent yearly depositions.

The continuation of sediment sampling and analysis, along with trending of data, is necessary to closely monitor contamination of SRS sediments. Cesium-137 releases from Z-Area have the potential to contaminate tributaries of McQueen Branch and possibly contaminate Upper Three Runs. The impact for possible contamination warrants long-term monitoring by ESOP along SRS streams and the publicly accessible Savannah River.

### **6.2.0 RESULTS AND DISCUSSION**

#### **6.2.1 Radiological Parameter Results**

SCDHEC 2014 radiological data can be found in Appendix A-ESOP data and statistical data can be found in Section 6.0.

Sediments were evaluated for gross alpha and gross non-volatile beta as well as a suite of 24 gamma-emitting radionuclides. Selected samples were also analyzed for plutonium-238 (Pu-238) and plutonium-239/240 (Pu-239/240). A complete list of gamma-emitting radionuclides that SCDHEC analyzed for in 2014 can be found in Section 5.0, Table 3.

Gamma spectroscopy analysis led to detections of man-made radionuclides. Cesium-137 activity trends highest at the SRS creek mouths, followed by SRS on-site streams, and publicly accessible boat landings. Figure 1 in Section 5.0 illustrates Cs-137 activity in sediment samples collected from SRS stormwater basins, SRS streams, SRS creek mouths and publicly accessible boat landings.

Samples collected from six of the seven on-site non-publicly accessible SRS stream sample locations had Cs-137 detections averaging 0.41 ( $\pm 0.37$ ) picocuries per gram (pCi/g) and ranged from less than minimum detectable activity (MDA) to 1.1 pCi/g at FourMile Creek (SMSV-2049). There were no Cs-137 detections in the three SRS stormwater basins in 2014.

Cesium-137 was detected at three of the five publicly accessible SRS creek mouth locations (Section 5.0, Figure 2). The Cs-137 averaged 0.89 ( $\pm 1.2$ ) pCi/g and ranged less than the MDA to 2.30 pCi/g at Steel Creek mouth (SMSV-2017). Cesium-137 was detected at nine of the ten publicly accessible boat landing locations at an average of 0.35 ( $\pm 0.61$ ) pCi/g and ranged from less than MDA to 1.94 pCi/g at Steel Creek Landing (SMSCL14).

The concentration of background terrestrial radionuclides varies from place to place in much the same way that mineral deposits can be expected to vary from geologic processes that occur over time. The average value of background radionuclides will fluctuate from site to site and its value is dependent on the data collected at a particular site.

Five out of six background samples had Cs-137 detections (Section 5.0, Table 2). The random background sample detection average was 0.12 ( $\pm 0.03$ ) pCi/g. The random background samples had detections ranging from less than MDA to 0.17 pCi/g. Cesium-137 activity, on average, was highest at the SRS creek mouth samples followed by SRS on-site stream locations.

There was one detection of Be-7 at the SMSV-118 location at 1.1 ( $\pm 0.50$ ) pCi/g.

There were detections of actinium-228, potassium-40, lead-212, lead-214, and radium-226. These are Naturally Occurring Radioactive Material (NORM) decay products that account for the remaining gamma detections (Section 5, Table 3). All other gamma-emitting radionuclides had no detections above their respective MDA.

Gross alpha activity was detected in two of seven on-site non-publicly accessible SRS stream samples locations averaging 26.3 ( $\pm 0.2$ ) pCi/g and ranging from 15.7 to 26.4 pCi/g. The highest detection was located at McQueen's Branch (SMSV-2069). Gross alpha activity was detected in one of three SRS stormwater basin sample locations (SME-004) at 0.14 pCi/L. Gross alpha activity was not detected in any of the six background locations. Gross alpha activity was detected in two of ten publicly accessible boat landings averaging 11.7 ( $\pm 1.5$ ) pCi/g and ranging from 9.01 to 12.7 pCi/g at Cohen's Bluff Landing (SMCB14). Gross alpha activity was not detected in any of the creek mouth samples. These results can be found in Section 5.0 Figure 3.

Gross non-volatile beta activity was detected in four of the seven on-site SRS stream locations averaging 14.4 ( $\pm 7.3$ ) pCi/g. Activities ranged from less than MDA to 24.7 pCi/g. The highest detection was located at Burton Ferry Landing (SMSV-118). All of the five creek mouth locations had gross non-volatile beta detections averaging 20.5 ( $\pm 3.6$ ) pCi/g. Activities ranged from less than MDA to 25.1 pCi/g. The highest detection was located at Lower Three Runs creek mouth (SMSV-2020). Gross non-volatile beta was detected in all three SRS stormwater basins averaging 14.1 ( $\pm 4.4$ ) pCi/g and ranging from less than MDA to 17.0 pCi/g at SME-004 basin (Section 5.0 Figure 3).

Gross-beta activity was detected in four of the six background locations averaging 15.3 ( $\pm 8.6$ ) pCi/g. Activities ranged from less than MDA to 28.0 pCi/g. The highest detection was located in Saluda county.

Isotopic analysis of Pu-238 and Pu-239/240 was performed on three SRS creek mouth locations. Plutonium-238 was detected in all of the sampling locations. Activities ranged from 0.004 pCi/g to 0.032 pCi/g at SMSV-2011. Plutonium-239/240 was detected in all of sampling locations. Activities ranged from 0.003 to 0.006 pCi/g at SMSV-2013.

### **6.2.2 Nonradiological Parameter Results**

A United States Environmental Protection Agency (USEPA) Target Analyte List of ten metals was analyzed in all of the SRS creek mouth locations and the public boat landings in 2014. Metals data can be found in Section 5.0, Figure 5. Comparisons were made to the Ecological Screening Value (ESV) for sediment which does not represent remediation goals or cleanup levels, but is used to identify constituents of potential concern (WSRC 2005). The South Carolina state averages are from “Elements in South Carolina Inferred Background Soil and Stream Sediment Samples” (Canova 1999).

Barium (Ba) was detected above the ESV of 20 milligrams per kilogram (mg/kg) in all of the five SRS creek mouth locations collected. The SRS creek mouth average was 102 ( $\pm 37$ ) mg/kg with a minimum of 54 mg/kg at FourMile Creek mouth (SMSV-2015) and a maximum of 140 mg/kg at Steel Creek mouth (SMSV-2017). The public boat landing average was 37 ( $\pm 25$ ) mg/kg with a minimum of 12 mg/kg at Cohen’s Bluff Boat landing (SMCB14) and a maximum of 100 mg/kg at Steel Creek boat landing (SMSCL14).

Beryllium (Be) was detected above the ESV of 0.5 mg/kg at two of the five SRS creek mouth locations. The SRS creek mouth average was 0.6 ( $\pm 0.2$ ) mg/kg and range from less than the Minimum Detection Limit (MDL) at FourMile Creek mouth (SMSV-2015) and a maximum of 0.83 mg/kg at Upper Three Runs Creek mouth (SMSV-2011). Beryllium was not detected above the ESV of 0.5 mg/kg at any of the ten public boat landing locations.

Cadmium (Cd) was found above the ESV of 0.6 mg/kg in all of the five SRS creek mouth locations collected. The SRS creek mouth average was 3.0 ( $\pm 1.1$ ) mg/kg with a minimum of 1.8 mg/kg at Upper Three Runs Creek mouth (SMSV-2011) and a maximum of 4.4 mg/kg at FourMile Creek mouth (SMSV-2015). Cadmium was detected in one of the public boat landing samples, Steel Creek boat landing (SMSCL14), at 2.0 mg/kg.

Chromium (Cr) was detected in all of the five SRS creek mouth locations and none were above the ESV of 36 mg/kg. The SRS creek mouth average was 16.9 ( $\pm 6.6$ ) mg/kg with a minimum of 9.4 mg/kg at FourMile Creek mouth (SMSV-2015) and a maximum of 26 mg/kg at Steel Creek mouth (SMSV-2017). The public boat landing average was 6.8 ( $\pm 3.5$ ) mg/kg and ranged from 2.8 mg/kg at Burton’s Ferry Landing (SMBFL14) to 14 mg/kg at Steel Creek boat landing (SMSCL14).

None of the 2014 SRS creek mouth samples was above the ESV of 18.7 mg/kg for copper (Cu). The SRS creek mouth average was 7.7 ( $\pm 4.2$ ) mg/kg with a minimum of 3.1 mg/kg at FourMile Creek mouth (SMSV-2015) and a maximum 14.0 mg/kg a Steel Creek mouth (SMSV-2017). The public boat landing average was 2.6 ( $\pm 1.3$ ) mg/kg with a minimum of 1.3 mg/kg at Jackson

Boat Landing (SMJBL14) and a maximum of 5.6 mg/kg at Steel Creek boat landing (SMSCL14).

All 2014 samples were below the ESV of 30.2 mg/kg for lead. Lead (Pb) was detected in four of the five SRS creek mouth samples at an average of 9.6 ( $\pm 2.0$ ) mg/kg and ranged from less than MDL at FourMile Creek mouth (SMSV-2015) and a maximum of 12.0 mg/kg at Steel Creek mouth (SV-2017). Eight of the ten public boat landings yielded detections for lead. The average was 8.0 ( $\pm 1.8$ ) mg/kg and ranged from less than MDL at Jackson boat landing (SMJBL14) and Burton's Ferry Landing (SMBFL14) and a maximum of 11.0 mg/kg at Johnson's landing (SMJL14).

Three of the 2014 SRS creek mouth samples exceeded the ESV of 630 mg/kg for manganese. Manganese (Mn) was detected in all SRS creek mouths and public boat landing samples. SRS creek mouth samples had an average of 908 ( $\pm 322$ ) mg/kg with a minimum of 540 mg/kg at Upper Three Runs Creek mouth (SMSV-2011) and a maximum of 1300 mg/kg at Lower Three Runs Creek mouth (SMSV-2020). The public boat landing average was 216 ( $\pm 299$ ) mg/kg with a minimum of 22 mg/kg at Jackson boat landing (SMJBL14) and a maximum of 1000 mg/kg at Steel Creek boat landing (SMSCL14).

Mercury (Hg) was not detected above the MDL in any samples collected in 2014.

All 2014 samples were below the ESV of 15.9 mg/kg for nickel. Nickel (Ni) was detected in all of the five SRS creek mouth samples. The SRS creek mouth average was 7.6 ( $\pm 2.4$ ) mg/kg with a minimum of 4.0 mg/kg at FourMile Creek mouth (SMSV-2015) and a maximum of 9.4 mg/kg at Lower Three Runs Creek mouth (SMSV-2020). The public boat landing average was 3.4 ( $\pm 1.6$ ) mg/kg with a minimum detection of 2.2 mg/kg at Johnsons boat landing (SMJL14) and a maximum of 6.8 mg/kg at Steel Creek boat landing (SMSCL14).

All 2014 samples were below the ESV of 98 mg/kg for zinc. Zinc (Zn) was detected in all of the SRS creek mouth samples. The SRS creek mouth average was 33 ( $\pm 17$ ) mg/kg with a minimum of 6.4 mg/kg at FourMile Creek mouth (SMSV-2015) and a maximum of 51 mg/kg at Steel Creek mouth (SMSV-2017). The public boat landing average was 12.5 ( $\pm 7.6$ ) mg/kg with a minimum of 5 mg/kg at Cohens Bluff boat landing (SMCB14) and maximum of 31 mg/kg at Steel Creek boat landing (SMSCL14). SCDHEC nonradiological sediment data can be found in ESOP Data- Appendix A and nonradiological statistical data can be found in Section 6.0.

### **6.2.3 SCDHEC and DOE-SR Data Comparison**

Radiological data comparison of 2014 sediment samples from SCDHEC and DOE-SR resulted in similar findings. SCDHEC Cs-137 data from the SRS creek mouths were trended for 2010-2014 (Section 5.0, Figure 4). Due to flooding disturbances in sediments and other media characteristics, variability in sediment samples can be anticipated.

DOE-SR and SCDHEC split seven SRS stream sediment and three stormwater basin sediment samples in 2014. All SCDHEC samples were analyzed for gross alpha and gross beta-emitting particles and gamma-emitting radionuclides. Select samples were also analyzed for Pu-238, Pu-239/40.

Both agencies detected Cs-137 concentrations in SRS streams, SRS stormwater basins and Savannah River locations. DOE-SR Cs-137 activity ranged from less than minimum detectable concentration (MDC) to 108 ( $\pm 6.9$ ) pCi/g at R-Area Downstream of R-1. This location is not accessible to the public. The publicly accessible Savannah River and SRS creek mouths averaged 0.89 ( $\pm 1.2$ ) pCi/g in the SCDHEC data. DOE-SR detected Cs-137 above MDC at 6 locations along the Savannah River and creek mouths at an average of 0.02 ( $\pm 0.004$ ) pCi/g. Cs-137 was not detected in any of the stormwater basins sampled by SCDHEC. The DOE-SR on site stormwater basins results ranged from less than MDC to a maximum Cs-137 concentration of 1500 ( $\pm 1.0$ ) pCi/g at the Z-Area Basin.

SCDHEC had no detections of Am-241 in sediment samples collected in 2014. The on-site DOE-SR stream sediments Am-241 detections ranged from less than MDC to 0.15 pCi/g R-Area Downstream of R-1. DOE-SR detected Am-241 in six Savannah River and SRS creek mouths samples above MDC. The average MDA for the 2014 SCDHEC sediment samples was 0.156 pCi/g, which is higher than the DOE-SR MDC of 0.0039 pCi/g (SRNS 2014). Since DOE-SR has a much lower MDC, this may explain why the SCDHEC data does not report more detections above the MDA. Also, values less than the MDC are included in the DOE-SR data (SRNS 2014). Only detections are averaged from the SCDHEC data.

### 6.3.0 CONCLUSIONS AND RECOMMENDATIONS

The creek mouths of SRS are a conduit for the dispersal of radionuclides into publicly accessible water. Cesium-137, Pu-238, and Pu-239/240 activity was found in the sediment within several creek mouths at the Savannah River.

Cesium-137 is the most abundant anthropogenic radionuclide found in the sediment samples. Cesium-137 levels of 2014 from all the samples collected outside of SRS boundaries are within the expected range consistent with previous SCDHEC background data and may be attributed, in part, to fallout from past nuclear events in the 1950s and 1960s. The highest average level of Cs-137 from all 2014 sediment samples occurred in the SRS creek mouth samples.

Metals in sediment can be naturally occurring or a result of man-made processes such as those used in SRS operations, which have released elevated amounts into streams on the SRS. Redistribution of sediment from flooding can carry contaminants to downstream locations. Geological factors in the Savannah River basin contribute to the levels of metals through erosion and sedimentation. All 2014 samples were below the ESV for chromium, copper, mercury, nickel, zinc and lead.

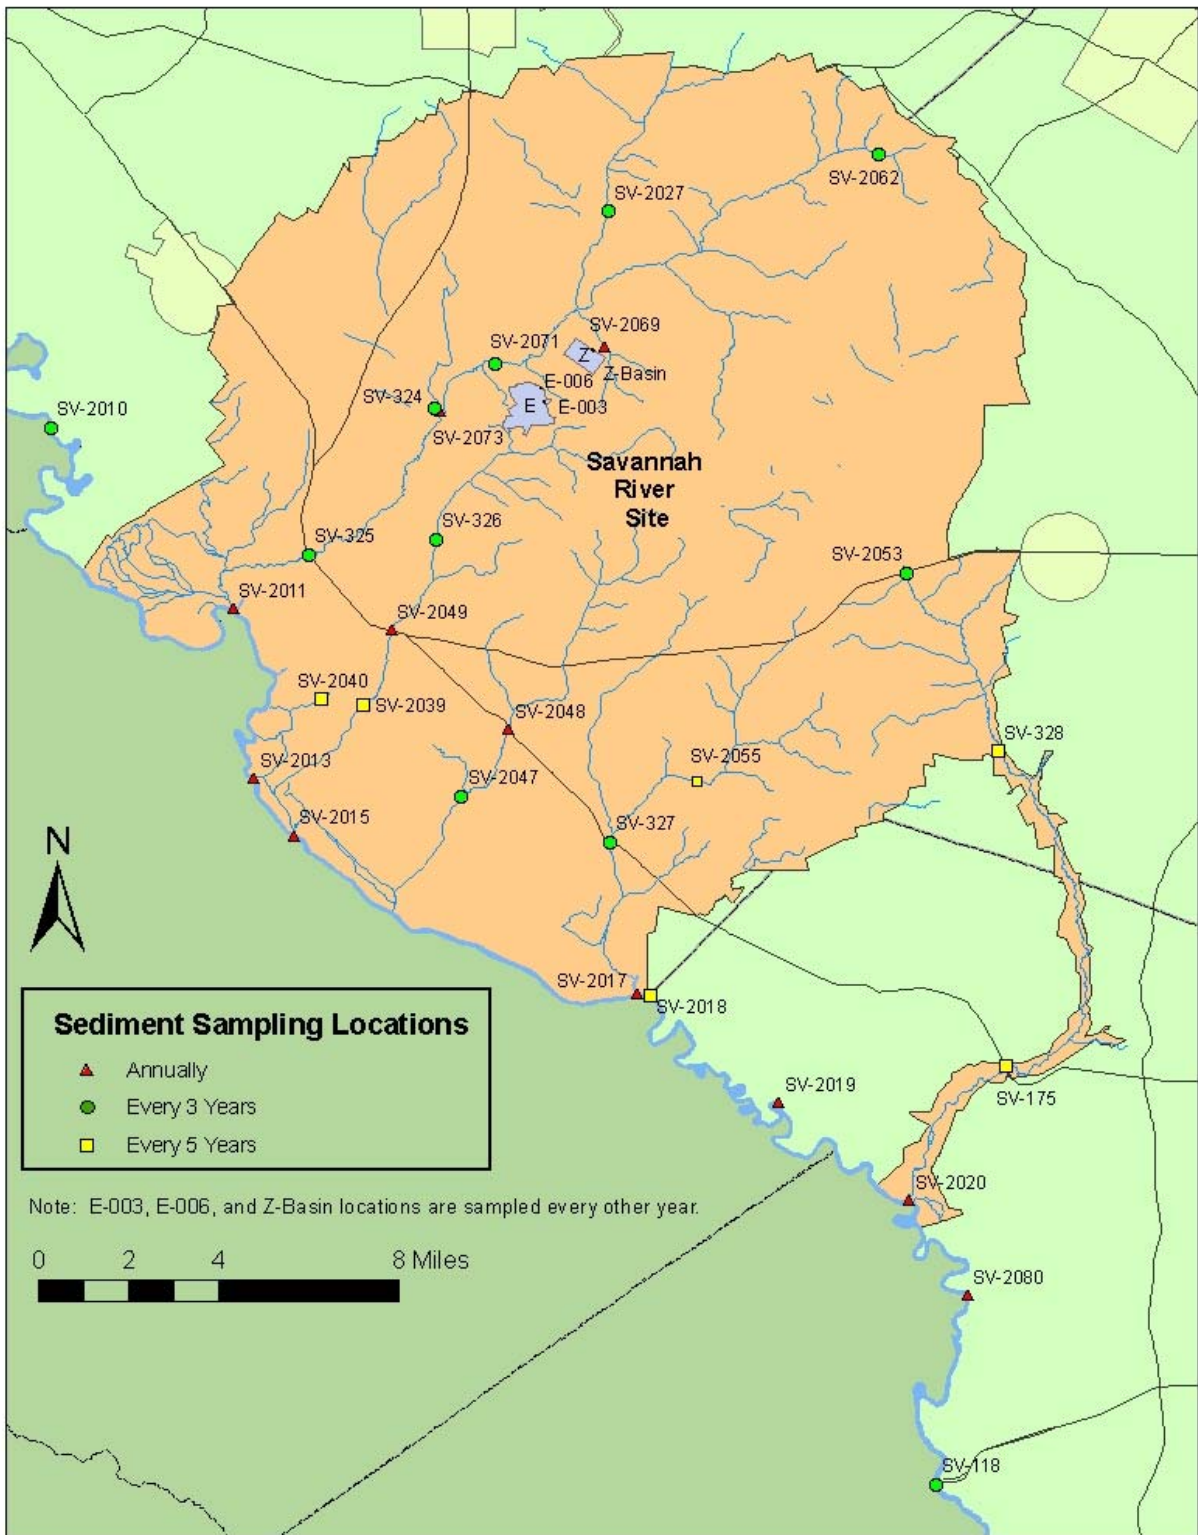

SRS sediments should continue to be monitored due to current releases of contaminants and the potential for future discharges from SRS operations, legacy wastes, and clean-up activities. Year-to-year data comparisons are difficult to interpret due to the nature of sediment. Differences among samples may be due to the fraction of clays that most effectively retain radionuclides. There is also difficulty in replicating the exact sampling point due to erosion and sedimentation.

Monitoring of on-site sediments is of great importance since over-land precipitation and streams transport contaminated sediment with radionuclides outside the SRS boundary.

ESOP will continue independent monitoring of SRS and Savannah River sediments and will periodically evaluate modification of the monitoring activities to better accomplish project goals and objectives. Continued monitoring will provide an improved understanding of radionuclide and non-radionuclide levels in SRS sediments and the Savannah River sediments which will impart valuable information to human health exposure pathways. Trending of data over multiple years demonstrates whether radionuclide concentrations in the SRS area are declining due to radioactive decay or possibly increasing due to disturbances on SRS. The comparison of data results allows for independent data evaluation of DOE-SR monitoring activities. To compare the environmental monitoring programs of ESOP and DOE-SR, the sediment samples from SRS will be collected in cooperation with DOE-SR personnel. Each program will then independently analyze the samples for radiological and nonradiological parameters and results will be compared in the 2015 ESOP Data Report. Cooperation between DOE-SR and SCDHEC provides credibility and confidence in the information being provided to the public.

South Carolina Department of Health  
and Environmental Control

### 7.1.0 PROJECT SUMMARY

The South Carolina Department of Health and Environmental Control (SCDHEC) Environmental Surveillance and Oversight Program (ESOP) provides independent evaluation of the Department of Energy – Savannah River (DOE-SR) environmental monitoring programs. ESOP personnel independently evaluated surface soils from ground surface to a 12 inch depth for gross alpha and gross non-volatile beta and select gamma-emitting radionuclides, as well as specific metals of concern at the Savannah River Site (SRS). These soil samples were collected to determine if SRS activities might have impacted areas outside of the site boundary. Radionuclide detections in soil are the result of accumulation over many years and do not represent yearly depositions.

Surface soil is an important medium that can be contaminated by radionuclides and metals, and transported to other ecological systems. Plants absorb contaminants from soil that in turn introduce contaminants to the food chain. Radionuclides and metals in soil can leach into groundwater and possibly emerge into surface water, potentially contaminating aquatic systems (Corey 1980). Air and water are subject to a much greater mixing than soil; therefore, dilution of metals does not occur as much in soil as in air or water. As a result, the accumulation of metals in surface soils is often more intense on both local and global scales than in the other components of the biosphere (Alloway 1995). The re-suspension and subsequent airborne contamination of materials due to cleanup processes that include soil excavation and disturbance during remediation and prescribed burns facilitates the movement of contaminants to areas outside of the SRS boundary.

The ESOP surface soil monitoring project changed in 2004 to include more random background soils (those greater than 50-miles from an SRS center point) within the boundaries of the state of South Carolina (SC). A 50-mile SRS center point area was chosen for comparison to the DOE-SR study area. Sampling outside of the 50-mile study area was implemented to allow data comparisons between the SRS perimeter and SC background contaminant levels in soils. ESOP initiated the random sampling system to determine if elevated levels of contaminants are attributable to SRS activities. SRS perimeter and SC background averages were used to determine if SCDHEC data were comparable to radiological data from DOE-SR. Since DOE-SR environmental monitoring division does not report metals data for surface soil, no direct data comparisons can be made. Assessment of radiological and nonradiological contaminants in surface soil is necessary to detect any impact from DOE-SR operations beyond the historically impacted areas within the SRS boundaries.

ESOP collected samples in 2014 from six random background sites outside of the 50-mile SRS center point radius. Nineteen nonrandom samples were collected from SRS perimeter locations (Section 5.0, Table 1). Nonrandom SRS perimeter sampling locations are depicted on Map 1 of Section 4.0. A list of all nonrandom sampling locations is located in Section 5.0, Table 1. The majority of samples had detectable amounts of cesium-137 (Cs-137), an anthropogenic radionuclide, that may be a legacy of releases by SRS and atmospheric fallout from past nuclear weapons testing (USEPA 2014a). An assessment of Cesium-137 activity in 2014 is comparable to levels detected by ESOP in the past. There were no surface soil samples collected in 2014 that were above the United States Environmental Protection Agency (USEPA) Preliminary Remediation Goals (PRGs) or the USEPA Regional Screening Levels (RSLs) (USEPA 2014b).

There were no soil samples in 2014 that exceeded the radiological USEPA Soil Screening Levels (SSLs) (USEPA 2014c). SSLs are more conservative screening values that are utilized when soil is in close proximity to groundwater (e.g. near rivers and other surface water bodies). USEPA PRGs are generic/default screening values for radioactive contamination in soil. USEPA RSLs are generic/default values for the toxicity of chemical contaminants in soil. The PRGs, RSLs and SSLs of select radionuclides and metals sampled by SCDHEC are listed in Section 5.0, Tables 2, 3 and 4.

There were no gross alpha-emitting radionuclides detected in the samples collected in 2014. Gross non-volatile beta was detected among all sample types.

Results for all metal analytes were below the USEPA RSLs. Metals data has been trended over time and the samples collected near the SRS perimeter are similar to those collected randomly throughout South Carolina.

A data comparison of 2014 surface soil data from SCDHEC and DOE-SR resulted in similar findings. Both data sets report average Cs-137 levels lower outside the 50-mile radius of SRS than within the SRS perimeter. SCDHEC data from 2014 perimeter samples show a slight decrease in the average level of Cs-137 from the 2013 data. DOE-SR reports in 2014 that Cs-137 concentrations are consistent with historical results. Metals data could not be compared to SCDHEC results since the DOE-SR environmental monitoring division does not analyze nonradiological contaminants.

## 7.2.0 RESULTS AND DISCUSSION

### 7.2.1 Radiological Parameter Results

All radiological data can be found in Appendix A-ESOP Data, and summary statistics found in Section 6.0.

Surface soils were evaluated for gross alpha and gross non-volatile beta as well as a suite of 24 gamma-emitting radionuclides. The suite of 24 gamma-emitting radionuclides is part of a gamma spectroscopy analysis performed by the Radiological Environmental Monitoring Division Laboratory in Columbia, SC (Section 5.0, Table 5). Radioisotopes were detected not only in samples collected around the perimeter of SRS, but in background samples as well. The USEPA PRGs are used as a screening tool that corresponds to certain levels of human health risk in regards to radioactivity in soil (USEPA 2014d). The conservative PRGs correspond to a risk for chronic soil ingestion for a residential scenario and a one in one million (1E-06) increased cancer risk. Uranium has both a PRG and an RSL because it is both carcinogenic and toxic (USEPA 2014d). In 2014, ESOP analyzed for all of the radioisotopes listed in Section 5.0, Table 5.

Cesium-137 is a man-made fission product. Atmospheric Cs-137 was released from the Separation Areas and was a key radionuclide released to water and air, mainly from F- and H-Areas (CDC 2006). Cesium-137 was detected in 17 of 19 SRS nonrandom perimeter samples at an average of 0.10 ( $\pm 0.03$ ) picocuries per gram (pCi/g) and ranged from less than Minimum

Detectable Activity (MDA) to 0.18 pCi/g . The highest detection was located at SSAIK0214 in Aiken County.

Five of the six background samples had Cs-137 detections (Section 5.0 Table 8). The random background sample detection average was 0.13 ( $\pm 0.05$ ) pCi/g. The random background samples had detections ranging from less than MDA to 0.21 pCi/g. The results are depicted in Section 5.0, Figure 1.

In addition, potassium-40, lead-212, lead-214, radium-226, and actinium-228 were the only other gamma-emitting radionuclides detected among surface soil samples. These are Naturally Occurring Radioactive Material (NORM) decay products that may account for these detections. All other gamma-emitting radionuclides had no detections above their respective MDA.

Gross alpha-emitting radionuclides were released to the air primarily from M-Area, the reactor areas, and the separations Areas (CDC 2006). Analyses were conducted on gross alpha-emitting radionuclides in surface soil samples collected during 2014. There were no detections of gross alpha emitting radionuclides in 2014.

Gross beta-emitting radionuclides were released from the Separations Areas (CDC 2006). Gross beta was detected in seven SRS nonrandom perimeter samples averaging 11.5 ( $\pm 4.0$ ) pCi/g. There was only one detection of gross beta-emitting radionuclides in any background soil samples collected in 2014. Results are depicted in Figure 2 of Section 5.0.

### 7.2.2 Nonradiological Parameter Results

Data for all metals detected can be found in Appendix A-ESOP Data. The summary statistics are found in Section 6.0. SRS perimeter averages of select metal results are depicted in Figure 3 of Section 5.0.

Ten metals were analyzed in 19 nonrandom SRS perimeter surface soil samples collected in 2014. A complete list of all nonradiological analytes can be found in Section 5.0, Table 6. Findings were compared to the USEPA RSLs that are used as a screening tool, corresponding to certain levels of human health risk in soils (USEPA 2014a). All sample results were below the conservative generic/default USEPA RSLs, corresponding to a risk for chronic soil ingestion for a residential scenario. ESOP 2014 samples had detections of barium, chromium, copper, lead, manganese, beryllium, nickel, and zinc. There were no detections above the Minimum Detection Limit (MDL) for cadmium and mercury in the SRS perimeter samples. The following discussion of individual analytes will be limited to those of potential concern due to SRS operations.

Barium has been a constituent of the H-Area Hazardous Waste Management Facility (WSRC 1993a). Barium was detected in all of the 19 SRS nonrandom perimeter samples at an average of 29.9 ( $\pm 16.9$ ) milligrams per kilogram (mg/kg) and ranged from 5.8 to 66 mg/kg. The highest detection was located at SSAIK0214 in Aiken County. All samples were well below the RSL of 15,000 mg/kg and also below the SC average of 38 mg/kg (Canova 1999).

Beryllium is a strong, lightweight metal used in nuclear weapons work as a shield for radiation and as a neutron source (Till et al. 2001). Beryllium was detected in five of the SRS nonrandom

perimeter samples at an average of 1.0 ( $\pm 0.66$ ) mg/kg. The RSL for beryllium in soil is 160 mg/kg.

Chromium solutions were used at SRS as corrosive inhibitors. Chromium was a part of wastewater solutions resulting from dissolving stainless steel. It was also used in cleaning solutions in the separation areas (Till et al. 2001). The legal disposal of fly ash on land as a result of burning coal is a contributor of both chromium and nickel to soils. Fly ash particles can travel considerable distance in the air and contain trace elements of chromium (Alloway 1995). Chromium was detected in all 19 SRS nonrandom perimeter samples at an average of 5.8 ( $\pm 2.3$ ) mg/kg and ranged from 1.5 to 9.10 mg/kg. The highest detection was located in SSAIK0214 in Aiken County. For comparison, the most conservative RSL screening level (Chromium VI) is 230 mg/kg. The SC average for total chromium in soil is 16 mg/kg (Canova 1999).

Copper, while naturally occurring, can also be released to the environment through the combustion of wood, coal and oil (Alloway 1995). D-Area and the other coal combustion powerhouses emitted copper and other heavy metals (Till et al. 2001). These mechanisms are possible sources of elevated copper in surface soils. Copper was detected in 17 SRS nonrandom perimeter samples at an average of 2.7 ( $\pm 1.0$ ) mg/kg and ranged from 1.4 to 4.8 mg/kg. The highest detection was located in SSALD14 in Allendale County. All samples were below the RSL of 3,100 mg/kg. The SC average for copper in soil is 9 mg/kg (Canova 1999).

Atmospheric emissions of lead from SRS occurred through coal and fuel combustion (Till et al. 2001). Lead can deposit in soil, (due to its immobility) and have a long residence time when compared to other pollutants. Lead tends to accumulate in soil where its bioavailability can exist far into the future (Alloway 1995). Lead was detected in 17 SRS nonrandom perimeter samples at an average of 7.2 ( $\pm 2.2$ ) mg/kg and ranged from less than MDL to 11 mg/kg. The highest detection was located at SSJAK14 in Aiken County. For comparison, the RSL is 400 mg/kg and the SC average for lead in soil is 16 mg/kg (Canova 1999).

Manganese has been released in the separations area processes and discharged to liquid waste tanks (Till et al. 2001). It is also a byproduct of coal burning. Manganese was detected in all 19 SRS nonrandom perimeter samples at an average of 81 ( $\pm 69$ ) mg/kg and ranged from 5.9 to 220 mg/kg. The highest detection was located at SSGP14 in Aiken County. The SC average for manganese is 100 mg/kg (Canova 1999), and all were below the RSL of 1,800 mg/kg.

The largest anthropogenic source of nickel globally is the burning of fuels and coal combustion (Alloway 1995). At SRS, nickel was directly released through M-Area effluent from the plating rinse tanks and through site use of diesel generators (Till et al. 2001). Nickel was detected in 15 of the 19 SRS nonrandom perimeter samples at an average of 3.2 ( $\pm 0.06$ ) mg/kg. The highest detection was located at SSALD14 in Allendale County. The SC average for nickel is 6 mg/kg (Canova 1999), and the RSL of nickel is 1,500 mg/kg.

Zinc was released in relatively small amounts to the separations area seepage basins as well as the M-Area seepage basin (Till et al. 2001). Zinc was detected in all 18 SRS nonrandom perimeter samples at an average of 7.5 ( $\pm 3.7$ ) mg/kg and ranged from less than MDL to 22.0

mg/kg. The highest detection was located at SSALD14 in Allendale County. The RSL is 23,000 mg/kg. All samples were below the SC average of 23 mg/kg (Canova 1999).

SRS facilities, such as F- and H- Area, tritium facilities, waste tanks, and the coal-fired power plants have emitted mercury to the atmosphere (Till et al. 2001). Atmospheric fallout contributes to mercury findings in surface soil. None of the surface soil samples collected in 2014 yielded detections above the MDL of 0.1 mg/kg for mercury. The SC average for mercury is 0.18 mg/kg (Canova 1999) and the RSL for mercury is 5.6 mg/kg.

Cadmium enters the atmosphere through fuel and coal combustion (Till et al. 2001). None of the surface soil samples yielded detections above the MDL of 1.0 mg/kg for cadmium. The SC average for cadmium is 1.0 mg/kg (Canova 1999) and RSL for cadmium in soil is 70 mg/kg.

### 7.2.3 SCDHEC and DOE-SR Data Comparison

Cesium-137 (Cs-137), cobalt-60 (Co-60), and americium-241 (Am-241) were the only gamma-emitting radionuclides that SCDHEC and DOE-SR shared in analytical results. DOE-SR did not have any detections of Co-60 above the Minimum Detectable Concentration (MDC). DOE-SR did detect Am-241 in nine of ten perimeter locations at an average of 0.003 ( $\pm$  .002) pCi/g as well as three of the 25 mile perimeter locations (.005 pCi/g). Since SCDHEC did not have any detections of Co-60 or Am-241 above the MDA, only the Cs-137 detections are compared. DOE-SR did not analyze for alpha or beta-emitting radionuclides, nor did they analyze for metals; therefore, no comparisons could be made. Soil samples from both programs varied by location and in number. DOE-SR collected 10 samples near the SRS perimeter and three samples within 25 miles. ESOP collected 19 nonrandom SRS perimeter samples. ESOP also sampled six background locations outside of the 50-mile SRS center point study area. When interpreting data, it should be taken into consideration that samples were collected from a variety of soil types and locations.

Cesium-137 was detected by both DOE-SR and SCDHEC. Cesium-137 was detected above the MDC in nine of ten DOE-SR perimeter samples. SCDHEC detected Cs-137 in 17 of 19 nonrandom perimeter SCDHEC samples. Cesium-137 was also detected in the SCDHEC background locations. For the 2014 samples, the SCDHEC nonrandom perimeter average for Cs-137 was 0.10 ( $\pm$  0.03) pCi/g. The average for all the SCDHEC background samples was 0.13 ( $\pm$  0.05) pCi/g. The DOE-SR Cs-137 average for all SRS perimeter samples was 0.23 ( $\pm$  0.10) pCi/g (SRNS 2014). The DOE-SR data average for Cs-137 activity falls within one standard deviation of the SCDHEC data. Comparative data can be found in Section 5.0, Tables 7 and 8.

Cesium-137 was the only consistently detected parameter over past years. Trending data for Cs-137 in SRS perimeter samples is in Section 5.0, Figure 4. SCDHEC has trended Cs-137 since 2009 (SCDHEC 1999-2015:2010). Data shows that SCDHEC levels of Cs-137 in perimeter surface soils from 2009 to 2014 averaged 0.36 pCi/g. DOE-SR data of Cs-137 in perimeter surface soils from 2009 through 2014 averaged 0.17 pCi/g (SRNS 2009-2014). DOE-SR data shows steady Cs-137 levels from 2009-2014 although Cs-137 activity in 2013 and 2014 (0.22 pCi/g) results were higher than the average of 0.17 pCi/g from 2009-2014. SCDHEC Cs-137 data during 2009-2014 shows a steady decline from Cs-137 levels of 0.86 pCi/g in 2009. The results found by both SCDHEC and DOE-SR are influenced by the number of samples used to

determine the average and by collecting samples from different locations. The average level of Cs-137 in surface soil can vary due to the highly variable nature of soils. Radiocesium bioavailability in soil is influenced by soil properties such as clay content, pH, organic matter, and soil microflora (Absalom et al. 2001). In previous years, increases of Cs-137 activity in the perimeter SCDHEC samples in 2009 could be due to the addition of samples in closer proximity to the boundary of SRS, specifically in the Steel Creek floodplain. In the previous years only random samples within 50-miles of the SRS center point were sampled to determine the yearly average. In 2009, the addition of sampling at public boat landings was initiated. Excursions outside normally expected levels, contributed through unplanned Cs-137 releases, occurred at boat landings downstream of SRS, specifically in the Steel Creek floodplain area. These areas have historically been impacted by SRS operations and higher than background results are to be expected. These yielded higher averages in 2009. DOE-SR does not collect samples at these locations.

### 7.3.0 CONCLUSIONS AND RECOMMENDATIONS

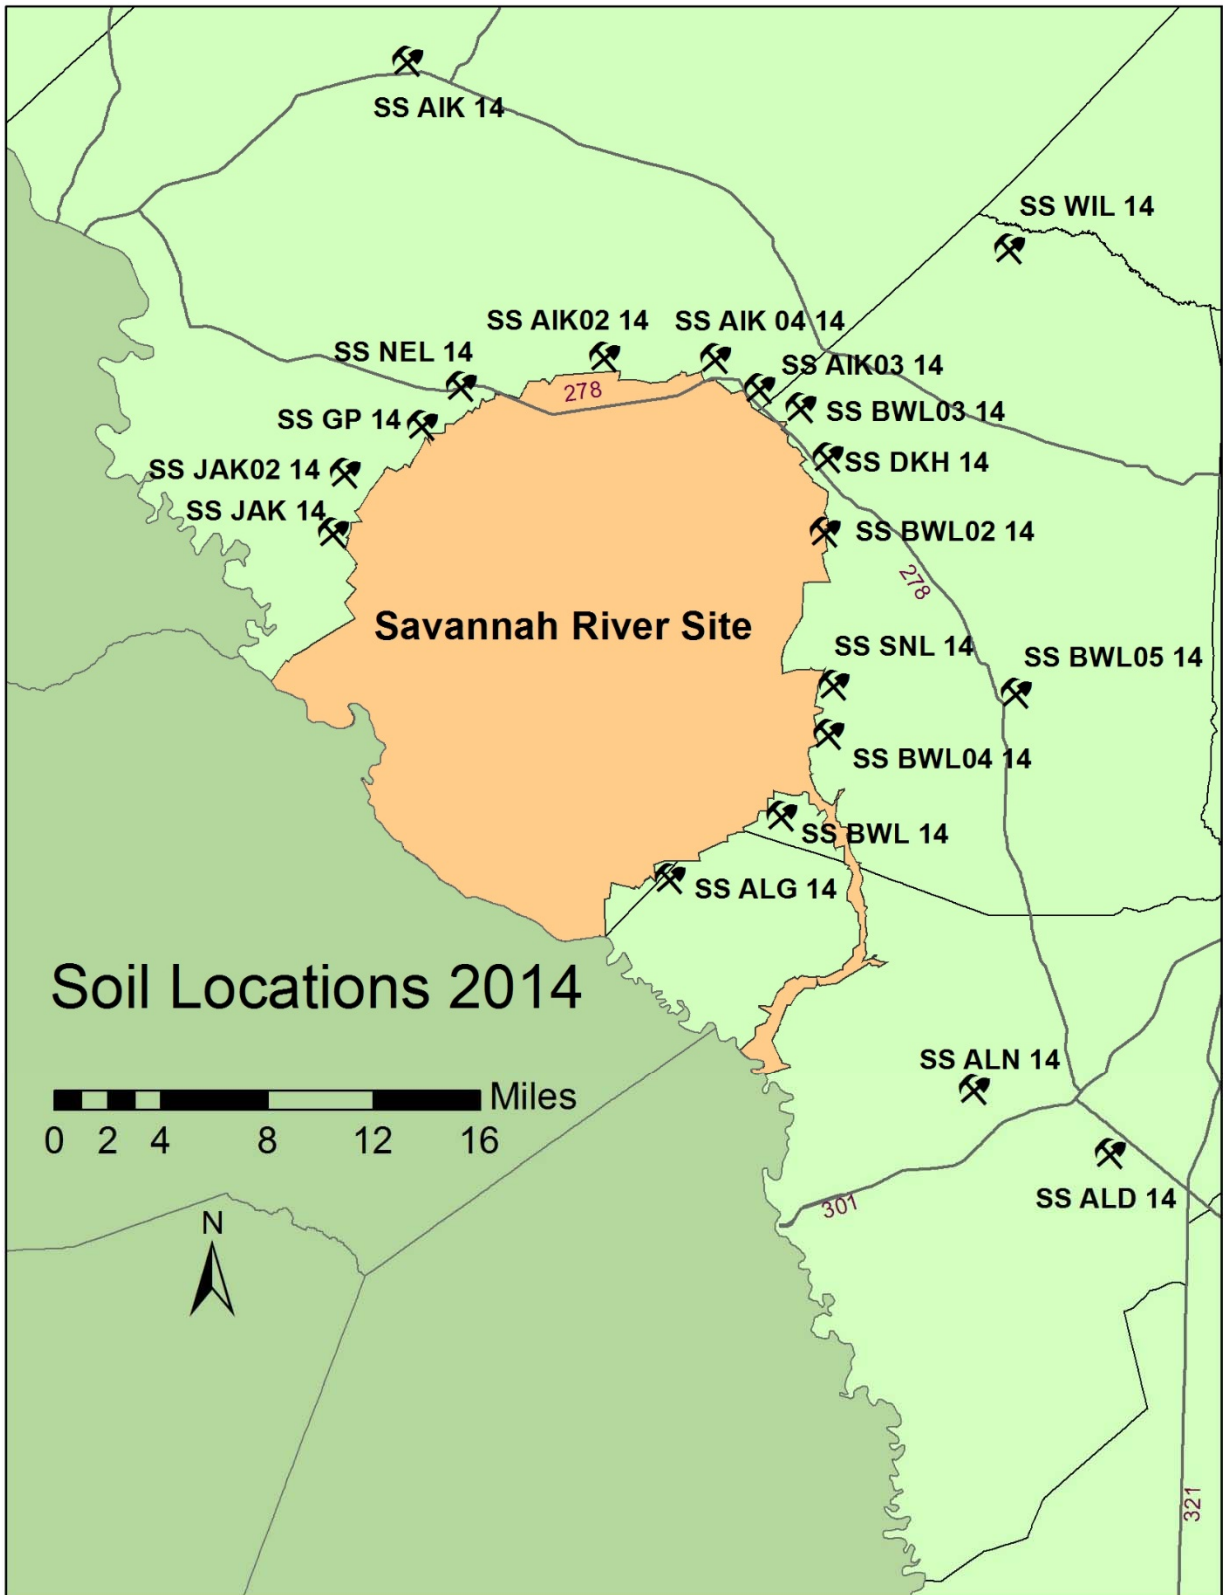

ESOP will continue independent monitoring of SRS perimeter surface soil and will periodically evaluate modification of the monitoring activities to better accomplish project goals and objectives. Monitoring will continue as long as there are activities at SRS that create the potential for contamination entering the environment. Continued monitoring will provide an improved understanding of radionuclide and non-radionuclide activity in SRS perimeter surface soils and the surrounding areas. Additional monitoring will impart valuable information to human health exposure pathways. Trending of data over multiple years will give a more definitive answer as to whether radionuclide concentrations in the SRS area are declining due to radioactive decay or possibly increasing due to flooding, soil disturbances and prescribed burns on SRS. The comparison of data results allows for independent data verification of DOE-SR monitoring activities. Cooperation between DOE-SR and SCDHEC provides credibility and confidence in the information being provided to the public.

In 2015, SCDHEC will continue to monitor the surface soil along the perimeter of SRS for radionuclides. Riverbank soil samples will be collected from the publicly accessible Savannah River watershed boat landings where human exposure is likely. The SCDHEC data at this time does not show there is an impact of elevated metal concentrations to areas outside of SRS. However, continued monitoring along the perimeter of SRS is still necessary due to the potential impact of SRS site operations to the surrounding environments. Possible atmospheric releases due to prescribed forest burning and soil disturbance at SRS could elevate metals in the surrounding area. Only through continued monitoring will this be determined. If perimeter samples show elevated metals concentration, additional samples will be evaluated.

# 2014 Radiological Monitoring of Terrestrial Vegetation Related to the Savannah River Site

## Environmental Surveillance and Oversight Program

97VG003

Taylor Stow, Project Manager

January 01, 2014 – December 31, 2014

**Midlands EQC Region-Aiken**  
**206 Beaufort St, N.E.**  
**Aiken, SC 29801**

### **8.1.0 PROJECT SUMMARY**

Terrestrial vegetation can be contaminated externally by direct deposition of airborne materials, water runoff, and precipitation that contains radioactivity. Vegetation can also be contaminated internally by uptake of radionuclides through the roots. Contaminated vegetation can be transported by physical means and, if eaten by animals, this radioactivity can enter the food chain.

The Department of Energy-Savannah River (DOE-SR) contracts for the collection and analysis of terrestrial vegetation, primarily Bermuda grass, to determine concentrations of radionuclides (SRNS 2014). The samples are obtained from 12 locations at the Savannah River Site (SRS) perimeter, one onsite location at the burial grounds, three 25-mile locations, and one 100-mile location. The Environmental Surveillance and Oversight Program (ESOP) of the South Carolina Department of Health and Environmental Control (SCDHEC) monitors for the presence of radionuclides in vegetation around SRS, collecting leaves from broad-leaved evergreen trees and shrubs, such as wax myrtle (*Myrica cerifera*), laurel oak (*Quercus laurifolia*), or Carolina laurelcherry (*Prunus caroliniana*).

In 2014, ESOP conducted independent vegetation monitoring at 17 locations along the perimeter of SRS, as well as three former SRS monitoring locations 25 miles from the center of SRS. These 25-mile samples allow comparisons to be made between tritium levels at the Site perimeter and tritium levels in the general SRS area. Samples were submitted for analysis three times in 2014 with samples obtained in February, March, June, November, and December. ESOP and DOE-SR perimeter stations sampled in 2014 are shown in Section 4.0, Map.

Samples from 14 of 17 perimeter stations exhibited tritium levels greater than the lower limit of detection (LLD; approximately 260 picocuries per liter (pCi/L)). Vegetation was also collected for gamma analysis at nine perimeter locations. Each gamma sample was analyzed for beryllium-7 (Be-7), sodium-22 (Na-22), potassium-40 (K-40), manganese-54 (Mn-54), cobalt-58 (Co-58), cobalt-60 (Co-60), zinc-65 (Zn-65), yttrium-88 (Y-88), zirconium-95 (Zr-95), ruthenium-103 (Ru-103), antimony-125 (Sb-125), iodine-131 (I-131), cesium-134 (Cs-134), cesium-137 (Cs-137), cerium-144 (Ce-144), europium-152 (Eu-152), europium-154 (Eu-154), europium-155 (Eu-155), lead-212 (Pb-212), lead-214 (Pb-214), radium-226 (Radium-226), actinium-228 (Ac-228), thorium-234 (Th-234), and americium-241 (Am-241).

Particular attention was paid to seven radionuclides: Be-7, K-40, Co-60, Cs-137, Pb-212, Pb-214, and Am-241, each of which has been detected in the past. During calendar year 2014, all except Co-60 and Am-241 were detected. Cs-137, a nonNORM fission product, was of particular importance.

Cs-137 was detected at one location on the northern side of SRS and at a background location in St. George, SC. Overall, both Cs-137 and tritium average detection activities have increased from last year, although it should be noted that the total number of Cs-137 detections decreased.

## **8.2.0 RESULTS AND DISCUSSION**

All monitoring data are in Appendix A-ESOP Data and summary statistics are in section 6.0. All established sampling locations are found in Appendix A-ESOP Data and Section 4.0, Map.

### **8.2.1 Tritium in Vegetation**

Tritium is a naturally occurring radioisotope of hydrogen that is normally found in very low concentrations (USEPA<sub>b</sub> 2012). Pre-bomb tritium levels are estimated to have been approximately 24 pCi/L in rainwater (DEQ 2013). Sources of man-made tritium include nuclear reactors and government weapons production plants. Tritium releases on SRS include both atmospheric and liquid contributions (SRNS 2014). Although the United States Environmental Protection Agency (USEPA) has not established a Maximum Contaminant Level (MCL) for tritium in solid media (e.g. vegetation), the MCL for drinking water has been set at 20,000 pCi/L (USEPA<sub>b</sub> 2012).

Tritium was detected in vegetation from 14 of the 17 perimeter sites sampled in 2014 (Section 5 Figures 1 and 2). The highest tritium levels detected during 2014 for each quarter were:

- Quarter 1 (March): AKN-004 at 1,599 ( $\pm$  203) pCi/L (wax myrtle)
- Quarter 2 (June): BWL-007 at 4,513 ( $\pm$  489) pCi/L (wax myrtle)
- Quarter 4 (November): BWL-008 at 2,760 ( $\pm$  926) pCi/L (laurel oak)

There were three tritium detections at two 25-mile stations: a 651 ( $\pm$  258) pCi/L detection at AKN-251 in November and a detection average of 317 ( $\pm$  161) pCi/L at ORG-251 in February and November. All three detections are at a level of activity significantly below the perimeter average of 1,147 ( $\pm$  259) pCi/L, falling slightly above the 160 pCi/L to 320 pCi/L range typically seen in the atmosphere today (DEQ 2013). The highest yearly average based on more than one detection was 968 ( $\pm$  281) pCi/L at AKN-005 (Section 6.0).

The highest single tritium detection in 2014 was 4,513 ( $\pm$  489) pCi/L from BWL-007, located on the southern side of SRS (Section 4, Map). The three highest averages based on more than one detection were 968 ( $\pm$  281) pCi/L from AKN-005 on the north side of SRS, 693 ( $\pm$  305) pCi/L from BWL-003 on the east side and 542 ( $\pm$  148) pCi/L from AKN-008 on the northwest side. Additional samples collected as background samples, in St. George, SC, Walterboro, SC, and at the Old Sheldon Church ruins in Beaufort County yielded two slight detections. The Old Sheldon Church ruins yielded a tritium value of 369 ( $\pm$  166) pCi/L and Walterboro had a detection of 546 ( $\pm$  325) pCi/L.

The average perimeter tritium detection increased from 769 ( $\pm$  123) pCi/L in 2013 to 1,147 ( $\pm$  259) pCi/L in 2014 (Section 5, Figures 1 and 2). Eleven locations (AKN-002, AKN-003, AKN-004, AKN-005, AKN-006, AKN-007, AKN-008, BWL-002, BWL-003, BWL-007, and BWL-008) showed increases relative to 2013, although six location averages are based on one detection (Section 6, Table 1). Two locations (BWL-001 and

BWL-009) showed decreased activity in 2014. Three locations (BWL-006, BWL-004, and ALD-001) showed no change.

Tritium analysis results from ESOP and DOE-SR sampling are presented in Section 5.0, Table 1. However, differences between the two programs in sampling dates, the vegetation sampled, and analysis methods should be considered during comparison. Provided there are detections, data comparison of associated locations from the two programs is conducted by converting from picocuries per gram (pCi/g) to pCi/L, using a dry/wet weight ratio of 0.3 furnished by DOE-SR, using the formula:

$$\text{pCi/L} = [\text{pCi/g} \times (1/0.3)] / (1 - 0.3) = \text{pCi/mL} \times 1000.$$

Two colocations (i.e. sample locations in relatively close proximity in space and time) are relevant to this report: the Patterson Mill Road and Allendale Gate locations. Both locations showed a tritium activity that was less than the lower limit of detection for DOE-SR and ESOP samples.

DOE-SR and ESOP sampled vegetation at ten comparable locations, including colocations, in 2014. At these locations, both programs reported no tritium detections above the lower limit of detection. All measures of central tendency and standard deviation were calculated using detections only. It should also be noted that temporal proximity was also taken into account when ESOP samples were “matched” to DOE-SR samples.

### **8.2.2 Gamma in Vegetation**

The naturally occurring isotopes potassium-40 (K-40) and beryllium-7 (Be-7) were detected where gamma samples were collected in 2014, but not from all locations. The lead (Pb) isotopes Pb-212, a member of the thorium decay series, and Pb-214, a member of the radium decay series, were also detected. Actinium-228 (Ac-228), a member of the thorium decay series, was detected at BWL-004 and BWL-006 in March and AKN-001 and AKN-002 in November. Because these are naturally occurring isotopes the results will not be discussed in this section, but are presented in Appendix A-ESOP Data.

The man-made isotopes Cobalt-60 (Co-60) and Americium-241 (Am-241) were not detected during 2014. (Appendix A-ESOP Data).

Cesium-137, which has an MCL of less than 4 mrem/year for drinking water (USEPA<sub>a</sub> 2013), was detected at one of the nine perimeter stations and at a background station in St. George, SC sampled for gamma in 2014. AKN-005 produced Cs-137 results greater than the Minimum Detectable Activity (MDA) for all three sampling events (Appendix A-ESOP Data). Cesium-137 is a man-made fission product and was a constituent of air and water releases on SRS, mainly from F and H-Areas. Liquid releases also occurred from the production reactors as a result of leaking fuel elements in the 1950s and 1960s (WSRC 1999).

Results of analysis for Cs-137 at AKN-005 showed lower levels than results from the previous calendar year (Section 5, Figure 3). The average Cs-137 level at AKN-005 decreased from 0.41 ( $\pm 0.04$ ) pCi/g in 2013 to 0.31 ( $\pm 0.03$ ) pCi/g in 2014. The average Cs-137 activity level for 2014 increased from 0.22 ( $\pm 0.02$ ) pCi/g in 2013 to 0.31 ( $\pm 0.03$ ) pCi/g, but the average for 2014 is based on three detections at one sampling location compared to seven detections at three separate sampling locations in 2013. The background location in St. George, SC showed a slight Cs-137 detection of 0.07 ( $\pm 0.02$ ) pCi/g in 2014; this location yielded no detection in 2013.

Gamma analysis results for Cs-137 from ESOP and DOE-SR sampling in 2014 are presented in Section 5.0, Table 2. DOE-SR detected Cs-137 at the Patterson Mill Road/BWL-004 colocation, at 0.25 ( $\pm 0.05$ ) pCi/g, and the Allendale Gate/BWL-006 colocation, at 0.27 ( $\pm 0.04$ ) pCi/g. ESOP results for both colocations were less than MDA. Differences in analysis, sampling methods, and the dates samples were obtained may account for any discrepancies between the data.

For the other DOE-SR stations, the closest ESOP stations were selected for comparison, except for the DOE-SR Highway 21/167 detection of 0.14 ( $\pm 0.03$ ) pCi/g (SRNS 2015). This gamma sampling location does not have a corresponding ESOP sampling location and any attempted comparison would be invalid. For this reason, it was not used for calculating the DOE-SR mean, median, and standard deviation and is also not shown in Section 5, Table 2.

DOE-SR detected Cs-137 at six of nine sampling stations that had a comparable ESOP location or colocation. ESOP had detections at one of nine comparable locations, although some ESOP locations correspond with more than one DOE-SR location. ALD-001, which has no comparable DOE-SR location, had no detections in 2014.

Average Cs-137 levels were also compared, using only detections to calculate the mean, median, and standard deviation (Section 5, Table 2). The DOE-SR average of 0.21 ( $\pm 0.05$ ) pCi/g (SRNS 2015) was not within one standard deviation of the ESOP average of 0.3 ( $\pm 0.04$ ) pCi/g; however, the ESOP average is based on one detection.

### **8.3.0 CONCLUSIONS AND RECOMMENDATIONS**

ESOP conducted independent vegetation monitoring in 2014 at 17 locations around the perimeter of SRS and three locations 25 miles from the center of SRS. Tritium was detected in vegetation from 14 of 17 of the perimeter stations and one of the 25-mile stations. The highest activity sample, at 4513 ( $\pm 489$ ) pCi/L, was collected on the south side of SRS at SCDHEC location BWL-007. The average tritium activity detected at the SRS perimeter increased from 769 ( $\pm 123$ ) pCi/L in 2013 to 1147 ( $\pm 259$ ) pCi/L in 2014. The average Cs-137 level was also higher in 2014, increasing to 0.31 ( $\pm 0.03$ ) pCi/g from 0.22 ( $\pm 0.02$ ) pCi/g in 2013, but the total number of detections was lower.

## **2014 ESOP Data Report- Radiological Monitoring of Terrestrial Vegetation Related to the SRS**

---

A comparison of ESOP and DOE-SR tritium data was performed (Section 5, Table 1). DOE-SR and ESOP did not detect tritium at either colocations or comparable locations in 2014 (SRNS 2015).

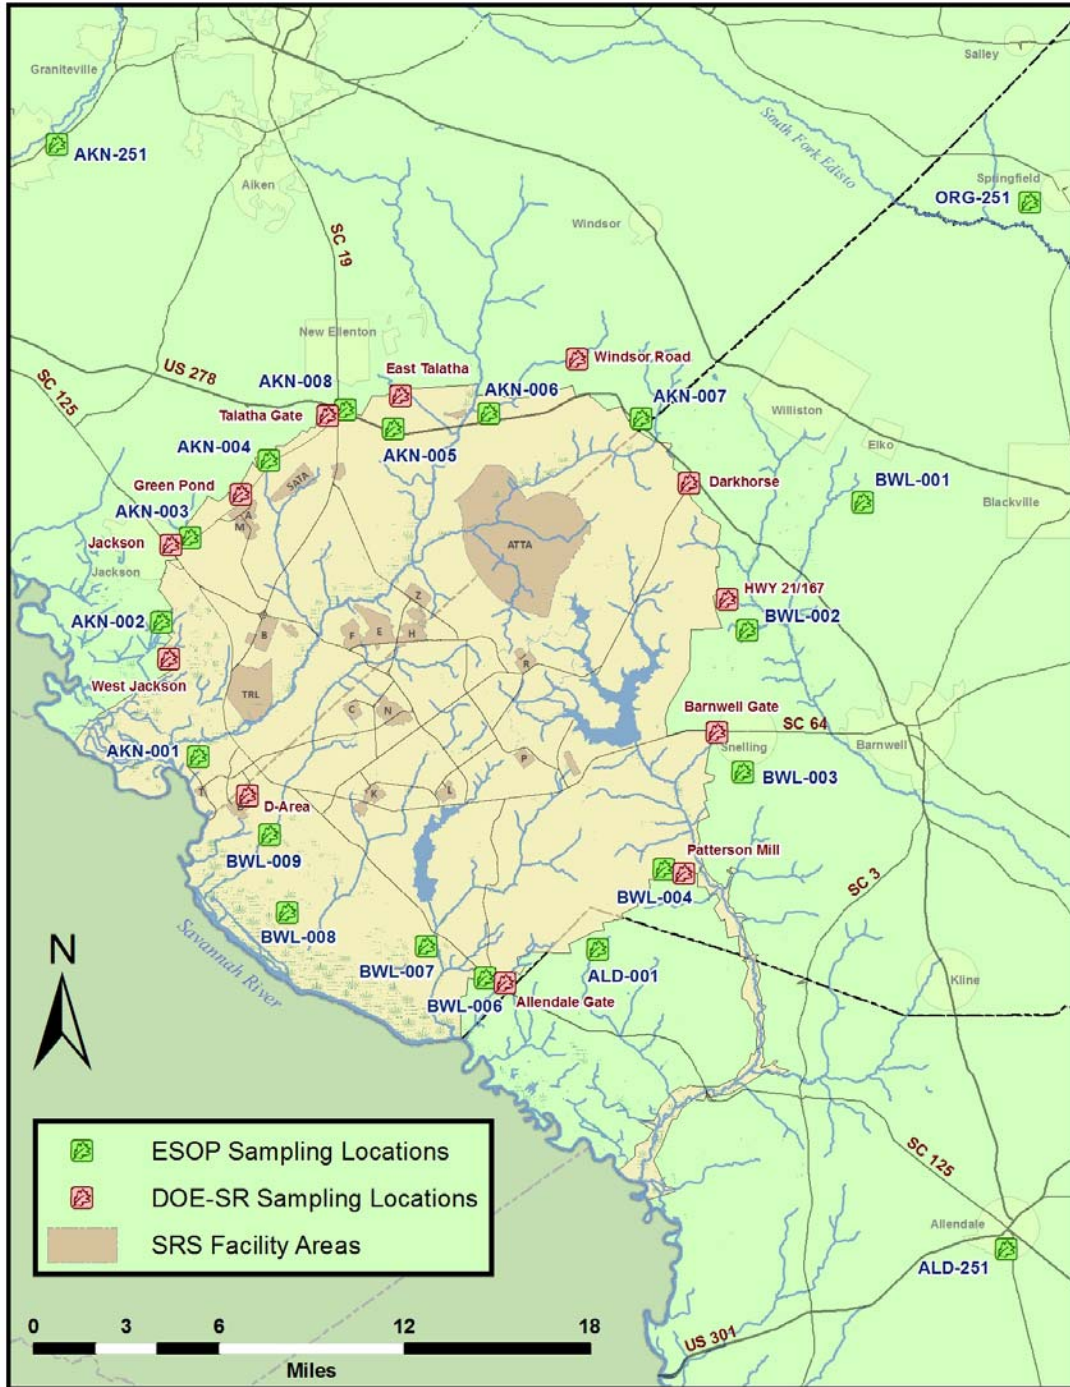

A comparison of DOE-SR data and ESOP Cs-137 data was also performed (Section 5, Table 2). The DOE-SR average was not within one standard deviation of the ESOP average; however, the ESOP average is based on one detection. All ESOP locations showed either decreasing or static Cs-137 activity in 2014.

ESOP and DOE-SR collect a different suite of terrestrial vegetation (e.g., ESOP collects leaves from trees, whereas DOE-SR conducts annual grass collections). Both sample sets are complimentary and allow indirect comparisons to be made.

# 2014 Radiological Monitoring of Edible Vegetation Adjacent to Savannah River Site

## Environmental Surveillance and Oversight Program

01EV002

Taylor Stow, Project Manager

January 01, 2014 - December 31, 2014

Midlands EQC Region - Aiken  
206 Beaufort Street, N.E.  
Aiken, SC 29801

South Carolina Department of Health  
and Environmental Control

### **9.1.0 PROJECT SUMMARY**

Radionuclide uptake by vegetation may occur by direct absorption into the plant through the foliage or roots, and grazing animal dose exposure occurs primarily by ingestion of the contaminated plant (Kathren 1984). Plant uptake of radionuclides depends upon many factors including species, tissue type, soil-water-plant relationships, soil type, and the chemical nature of the radionuclide in the soil (Hanlon 2004). “Sampling and analyzing native vegetation can provide information about the presence and movement of radionuclides in the environment” (Lawrence Livermore National Laboratory, LLNL 1997).

Since 1988, when the last heavy water reactor at the Savannah River Site (SRS) was shut down, the tritium supply was re-established using the new Tritium Extraction Facility (TEF). This facility’s mission is to transfer new tritium gas to the nation’s tritium inventory (WSRC 2006). Potential atmospheric releases from this facility have the capability to impact the surrounding areas through aerial deposition.

The Radiological Monitoring of Edible Vegetation (EV) Project is a component of the South Carolina Department of Health and Environmental Control’s (SCDHEC) Environmental Surveillance and Oversight Program (ESOP) that monitors edible food in perimeter and background locations around the Savannah River Site. SCDHEC ESOP monitoring addresses public concerns pertaining to SRS operations through independent monitoring of radionuclide activities in edible vegetation found around the perimeter of SRS. ESOP compares data with the Department of Energy-Savannah River (DOE-SR) annually to address these concerns.

ESOP defined a study area comprised of perimeter counties <50-miles from the SRS center point, and background locations >50-miles from the SRS centerpoint. Section 4.0, Map depicts the counties around the perimeter of SRS and the United States Geological Survey (USGS) 7.5-minute quadrants that overlay those counties (USDOI 1992).

Edible vegetation was collected based solely on availability, and was directly dependent upon the growing season. Farmers, gardeners, and/or businesses surrounding the perimeter of SRS contributed some domestically grown crops. Wild edible vegetation is collected to monitor potential consumer exposures. Typical domestic crops collected in 2014 include collards, squash, tomatoes, and grapes. Wild food sources include plums and blackberries.

The SCDHEC detections in the study area are used to establish depositional pattern trends from the SRS boundary and South Carolina (SC) background. The subtraction of background from analysis results helps to separate atomic test fallout contamination levels and other sources (e.g. ongoing permitted releases at other nuclear facilities) from SRS source potential contamination (Federal Register 1968). However, fallout dispersion patterns and concentrations are weather related and not uniform, and no assignment of specific source may be made.

All detections reported are above the lower limit of detection (LLD) for tritium in water from distilled vegetation or the minimum detectable activity (MDA) for gamma radionuclides.

Tritium was detected above the LLD in perimeter samples of fruits and nuts (Section 6.0, Table 2).

All of the detected radionuclides except tritium originated from naturally occurring radioactive material (NORM). NORM radionuclides were the source of most public exposure. NORM was not discussed herein as radionuclides of concern unless greater than a South Carolina background.

## **9.2.0 RESULTS AND DISCUSSION**

Section 5.0, Tables 1-3 show the radionuclides of concern, the guideline levels, the intervention levels and their conversion to picocuries per gram (pCi/g) for data comparison. The International Atomic Energy Agency (IAEA 2009) has established guideline levels for radionuclides in foods (alpha-, beta-, and gamma-emitters) for general consumption, emphasizing the cumulative radioactivity guideline limits (Section 5.0, Table 2).

The US Food and Drug Administration (USFDA 2005) also has guidance levels for specific radionuclides called derived intervention levels (DILs). The USFDA adopted DILs to help determine whether domestic food in interstate commerce or food offered for import into the United States presents a safety concern (Section 5.0, Table 3).

References to vegetation in this report refer to the edible parts of plants. The general county and area statistics comparing radionuclide concentrations are in Section 6.0. All of the detections described herein are below the IAEA and USFDA guidelines for the specific radionuclide in food (Section 5.0, Tables 2 and 3). The actual data for this project can be found in Appendix A – ESOP Data.

### **9.2.1 2014 Tritium**

Tritium (H-3) is naturally present as a very small percentage of hydrogen in water, both liquid and vapor (ANL 2007). Historically, the main sources of tritium releases from the SRS operations were the reactor areas, the chemical separation facilities, and the tritium packaging areas. Tritiated water reacts chemically in living cells the same as nonradioactive water, and it is more hazardous biologically than tritium gas (CDC SRSHEs 1997). There were only five tritium detections out of 28 sample scans of edible vegetation collected by SCDHEC in 2014.

Leafy green plants and other vegetables from perimeter locations had no tritium detections from 13 samples, and fruits/nuts samples had five detections out of 15 samples collected.

For 2014, Aiken County had the highest frequency of detections (4 out of 10) across all categories. The highest perimeter detection was from a wild blackberry sample in Aiken County at 22,618 pCi/g (22,618 pCi/L). Areas not sampled to the southwest were in Georgia. The observed levels of tritium in edible vegetation were below the IAEA Radionuclides Guidelines for Food based on a direct unit conversion (Section 5.0, Table 2; 270 pCi/g). This limit would equal  $\{270 \text{ pCi/g} \times (1 \text{ g/1ml}) \times (1000 \text{ ml/L})\} = 270,000 \text{ pCi/L}$ , and all tritium detections were  $\leq 22,618 \text{ pCi/L}$  (Section 6.0, Table 1). Note that 1g/1ml is one gram per one milliliter, and ml/L is milliliter per liter, but the actual content of tritium in food would be relative to the percent moisture and the food wet weight.

### 9.2.2 2014 Gamma

The gamma-scan (24 radionuclides; Section 5.0, Table 1) detections found in naturally occurring radioisotopes (K-40 and Pb-214) are part of the South Carolina normal background exposure. There were no non-NORM radionuclide detections in 2014. Only samples with radionuclide detection results are included in the data tables (Appendix A – ESOP Data). All other gamma scan results were less than the MDA.

### 9.2.3 Cesium-137

Cesium-137 (Cs-137) is an alkali metal that is chemically and metabolically similar to potassium. If ingested, it is distributed relatively uniformly throughout the whole body including bone marrow (Federal Radiation Council 1965). The largest source of Cs-137 in the environment was fallout from atmospheric nuclear weapons tests in the 1950's and 1960's that dispersed and deposited Cs-137 worldwide. The many Cs-137 potential contributions to the environment may be passed down through linked critical exposure pathways. However, cesium is poorly absorbed by vegetation from the soil. Cesium is relatively uniformly distributed throughout all portions of the plant and does not tend to bioconcentrate except in some grains and mushrooms. Grains tend to have relatively high concentrations, but fruits and root vegetables, having a higher water content, tend to have low concentrations of cesium (Kathren 1984). Some fungi appear to bioconcentrate cesium and contribute the highest Cs-137 radioactive exposure through wild mushrooms compared to other food types (Botsch 1999). The concentration of Cs-137 in surface soil from fallout ranges between 0.1 to 1 pCi/g and averages less than 0.4 pCi/g. Cesium is generally one of the less mobile radioactive metals in the environment. Cesium preferentially adheres quite well to the soil organic layer, and the concentration associated with sandy soil particles is estimated to be 280 times higher than in interstitial water. Concentration ratios are much higher in clay and loam soils (ANL 2007). In 2014, there were no Cs-137 detections; however, previous years have observed detections in wild fungi samples.

### 9.2.4 SCDHEC and DOE-SR Data Comparison

Comparisons are based on tables and data sections of this report, and the DOE-SR Environmental Report 2014 (SRNS 2015). Direct comparisons between SRNS and SCDHEC could not be made due to variation in sampling and analysis methodologies.

DOE-SR, as compared to SCDHEC, has five defined quadrants where samples are collected annually: four quadrants are within 10 miles of SRS in each direction (NE, NW, SE, SW) along with one quadrant located within 25 miles SE. In 2014, DOE-SR edible vegetation exhibited radiological detections of tritium, Cs-137, Strontium-89/90 (Sr-89/90), Uranium-234 (U-234), Uranium-235 (U-235), Uranium-238 (U-238), Neptunium-237 (Np-237), Americium-241 (Am-241), Curium-244 (Cm-244), Plutonium-238 (Pu-238), Plutonium-239 (Pu-239), Technetium (Tc-99), and Gross Beta. Tritium detections occurred in greens and soybeans (SRNS 2015). DOE-SR tritium detections (two of five samples) in greens averaged 0.066 pCi/g ( $\pm 0.013$  pCi/g), with a median of 0.066 pCi/g, and a maximum of 0.076 pCi/g, and soybeans (two of five samples) averaged 0.034 pCi/g ( $\pm 0.018$  pCi/g), with a median of 0.034 pCi/g, and a maximum of 0.047 pCi/g. SCDHEC reported no tritium detections for leafy greens/vegetables in 2014. There were five SCDHEC fruit and nuts tritium detections (two wild types) from 15 samples that

averaged 7,212 pCi/L ( $\pm 9,926$  pCi/L); however, DOE-SR reported no tritium detections for fruits and nuts in 2014. Note that leafy green plants and domestic crops generally have a small canopy for absorption compared to larger tree canopy fruits, especially wild types. Also, wild type plants have a longer residence time (life cycle) for potential exposure than domestic crops.

The DOE-SR gamma and other beta-emitting radionuclide detections in edible vegetation were:

- Cs-137 was detected in four of five greens samples (0.057 pCi/g  $\pm 0.028$  pCi/g) with the maximum being 0.091 pCi/g from the 10 mile NW location; and one soybean sample (0.011 pCi/g) from the 10 mile SE location.;
- Sr-89/90 was detected in four of five greens samples (0.403 pCi/g  $\pm 0.510$  pCi/g) with a maximum of 1.16 pCi/g from the 10 mile NW location;
- U-234 was detected in all five greens samples (0.015 pCi/g  $\pm 0.009$  pCi/g) with a maximum of 0.025 pCi/g from the 25 mile SE location; three soybean samples (0.003 pCi/g  $\pm 0.002$  pCi/g) (all within 10 miles) with a maximum of 0.006 pCi/g from the 10 mile NE location; and one peanut sample (0.001 pCi/g) from the 10 mile SW location;
- U-235 was detected in one greens sample (0.002 pCi/g) from the 25 mile SE location; and one soybean sample (0.002 pCi/g) from the 10 mile NW location;
- Np-237 was detected in one soybean sample (0.002 pCi/g) from the 25 mile SE location.
- U-238 was detected in all greens samples (0.014 pCi/g  $\pm 0.012$  pCi/g) with a maximum of 0.0324 pCi/g from the 25 mile SE location; two soybean samples (0.001 pCi/g  $\pm 0.0002$  pCi/g) with a maximum of 0.002 pCi/g from the 10 mile NW and SE locations and one peanut sample (0.0009 pCi/g) from the 25 mile SE location;
- Pu-238 was detected in one soybean sample from the 25 mile SE location (0.003 pCi/g);
- Pu-239 was detected in one watermelon sample from the 10 mile SW location (0.00009 pCi/g);
- Am-241 was detected in one soybean sample from the 25 mile SE location (0.003 pCi/g);
- Cm-244 was detected in one soybean sample from the 25 mile SE location (0.002 pCi/g);
- Tc-99 was detected in four of five greens samples (0.419 pCi/g  $\pm 0.048$  pCi/g) with a maximum of 0.484 pCi/g from the 10 mile NE location; one peanut sample (0.150 pCi/g) from the 10 mile SW location, and all five soybean samples (0.230 pCi/g  $\pm 0.058$  pCi/g) with a maximum of 0.305 pCi/g from the 10 mile NW location;
- Gross Beta was detected in all five samples of greens, watermelon, peanuts and soybeans.

Note: In the preceding information, if there was more than one detect for the given radionuclide, an average was reported for all sample detections along with the standard deviation. If there was just one detection, only the detection was given for that sample.

The IAEA Radionuclides Guidelines for Food are 27 pCi/g total for Cs-137, Cs-134, S-35, Co-60, Sr-89, Ru-103, Ce-144, and Ir-192; 2.7 pCi/g total for Sr-90, Ru-106, I-129, I-131, and U-235; and 270 pCi/g for tritium (Section 5.0, Table 2). The USFDA Derived Intervention Levels for food are 32.4 pCi/g total for Cs-134 plus Cs-137, and 4.32 pCi/g for Sr-90 (Section 5.0, Table 2). All DOE-SR and SCDHEC food sample radionuclide detections respective totals were less than these limits.

### **9.3.0 CONCLUSIONS AND RECOMMENDATIONS**

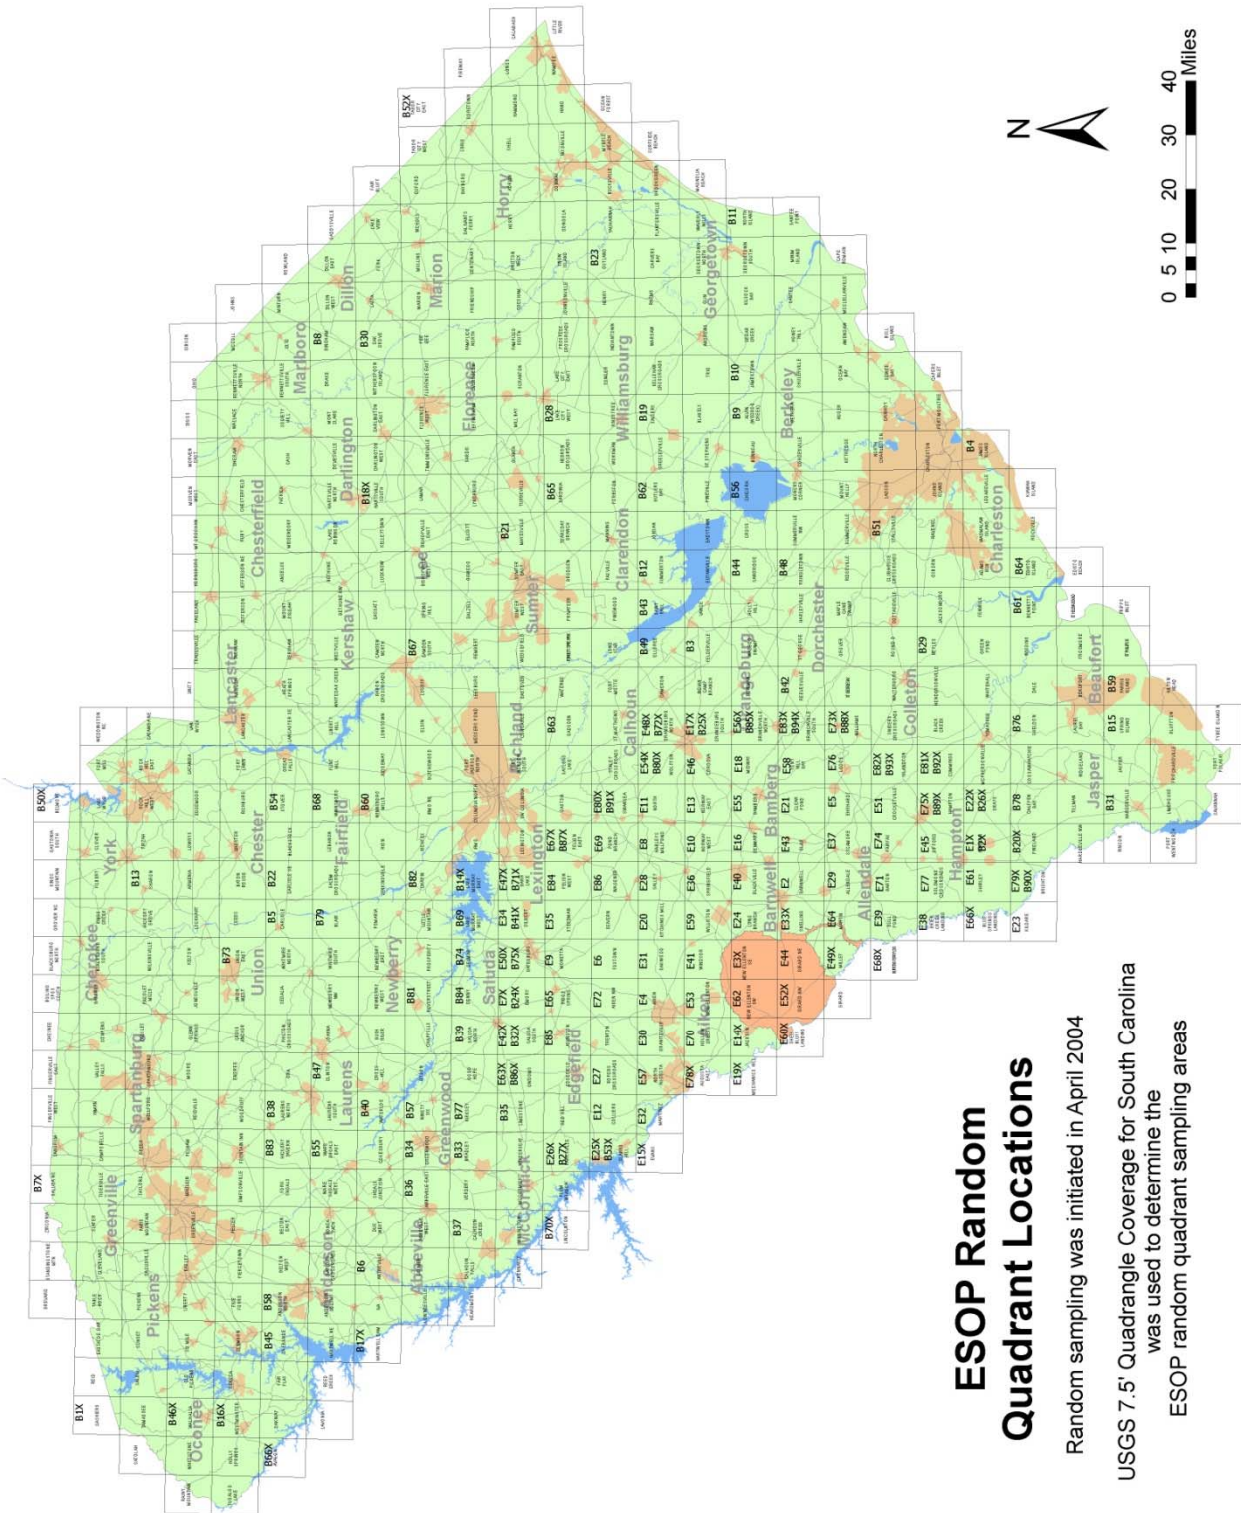

Detected radionuclide concentrations found in edible vegetation sampled around SRS are below the IAEA and USFDA standards for these emitters. Tritium continues to be the prevailing detectable analyte across all edible vegetation.

The highest tritium sample occurred in a wild blackberry sample at 22,618 pCi/L or 22.618 pCi/g. Three domestic edible vegetation tritium detections were observed with the highest detection being a grapes sample at 602 pCi/L or 0.602 pCi/g. All detections are below the IAEA Radionuclide food guideline of 270 pCi/g (Section 6.0, Summary Statistics).

SCDHEC and DOE-SR have different edible vegetation sampling schemes. The DOE-SR samples primarily domestic plants and has annual participants in quadrants at 0-10 miles from the perimeter of the SRS and one quadrant at 25 miles. SCDHEC participants supply domestic plants, and the 2014 vegetation collections included perennial wild edible vegetation found usually within 10 miles of the SRS border. Backgrounds were generally along a 50-mile perimeter with one annual background participant in Laurens County.

In the future, SCDHEC will explore opportunities to split samples with DOE-SR, use similar mapping techniques and establish colocated sampling locations for better comparisons between the two. In addition, SCDHEC may collect wild fungi due to its inherent ability to bioconcentrate Cs-137. DOE-SR might consider sampling some wild vegetation for better comparisons with SCDHEC.

9.4.0 Map

### ESOP Random Quadrant Locations

Random sampling was initiated in April 2004

USGS 7.5' Quadrangle Coverage for South Carolina was used to determine the ESOP random quadrant sampling areas

# 2014 Radiological Monitoring of Dairy Milk

## Environmental Surveillance and Oversight Program

97MK007

Kevin Baird, Project Manager

January 01, 2014 - December 31, 2014

**Midlands EQC Region – Aiken**  
**206 Beaufort Street N.E.**  
**Aiken, SC 29801**

### 10.1.0 PROJECT SUMMARY

Operations at the Savannah River Site (SRS) have resulted in the potential for radiological constituents to be released to the surrounding environment. Milk from dairies around SRS is routinely analyzed for levels of radioactivity that could impact human health. This project provides radiological monitoring of milk from selected dairies within a 50-mile radius of SRS in South Carolina (SC).

During 2014, DOE-SR collected samples from eight dairy locations in SC and Georgia (GA). Only four of these dairies are located within SC. Department of Energy-Savannah River (DOE-SR) milk samples are collected quarterly within a 25-mile radius of SRS. South Carolina Department of Health and Environmental Control's (SCDHEC) Environmental Surveillance and Oversight Program (ESOP) collects milk at four dairy locations, quarterly, within South Carolina to provide an independent source of data on radionuclide concentrations in milk. Three of these locations are within a 50-mile radius of the SRS center point and one is a background location beyond the 50-mile radius. This project provides analytical data for trending and comparison to published DOE-SR data. The 50-mile radius also allows SCDHEC to use the data in this report to compare the potential dose from milk consumption to the potential dose calculated by DOE-SR.

Consumption of milk products containing radioactive materials can be a major human exposure pathway. When an atmospheric release occurs, radionuclides can be deposited on pastures and ingested by grazing dairy animals. The animals may then release a portion of the radionuclides into their milk that could then be consumed by humans (CDC 2001). Radionuclides could also enter milk through the irrigation of a pasture using groundwater containing radioactive materials or uptake by plants from soil containing radioactive materials.

Absorption of different radionuclides by plants and animals is based on the chemical configuration of the isotopes and not on their radioactivity. Radioactive strontium is a calcium analogue and has a tendency to accumulate in bones and teeth. Strontium-90 (Sr-90) concentrates in bones when there is a deficiency of calcium in the diet of the individual. This pathway is of particular importance in the case of infants and children because they are more likely to drink large quantities of milk due to their active development of bones and teeth (Larson 1958). Cesium-137 (Cs-137) is less readily taken up by plant roots than Strontium-90, but the opposite is true for direct absorption from foliar (leaf) deposits. Cesium-137 is transferred rapidly from pasture grass to the muscles of animals (Kathren 1984). Iodine-131 (I-131) is rapidly transferred to milk and can quickly accumulate in the thyroid. Cobalt-60 (Co-60) is unlikely to accumulate in the environment, but if consumed, depending on the individual's health, it can be absorbed into the blood and tissues before it is slowly eliminated (USEPA 2002c). Tritium (H-3) is a radioisotope of hydrogen that produces beta particles, and therefore, can impact anything containing water or hydrocarbons. Tritium exists naturally in the environment, however large amounts of it were produced and released during the Cold War era through activities associated with the SRS. Its volatility quickly achieves equilibrium in the environment and the body, which makes it a particular health concern (Kathren 1984).

SCDHEC personnel collected unpasteurized milk samples on a quarterly basis in 2014. All milk samples from each quarter were analyzed for tritium, strontium-89/90 (Sr-89/90), and gamma-emitting radionuclides. While a select group of gamma-emitting radionuclides (I-131, Cs-137, and Co-60) are analytes of concern in dairy milk for this project, all other detections such as Potassium-40 (K-40) are considered naturally occurring radioactive material (NORM). Naturally occurring radionuclides are the source of most public exposure; however, they are not discussed in this report unless detections are significantly greater than those of the background location detections. SCDHEC analyzes samples for total strontium (Sr-89/90), instead of just Sr-90. This is done in order to provide a more conservative result, and it is assumed the total strontium detected is in the form of Sr-90.

DOE-SR did not detect tritium in any milk samples out of the 32 collected in 2014. Unlike SCDHEC, DOE-SR did have one detection of the gamma-emitting radionuclide Cs-137 in a Georgia dairy during the 2014 sampling period. DOE-SR had 3 detections of Sr-89/90 in 32 milk samples, and all detections were located in SC dairies (SRNS 2014).

### 10.2.0 RESULTS AND DISCUSSION

#### 10.2.1 Tritium Results

One SCDHEC milk sample out of 16 collected during 2014 exhibited tritium activity above the Lower Limit of Detection (LLD) (Appendix A – ESOP Data). This single detection of 370 pCi/L occurred at the Govan, SC perimeter location. The summary statistics located in section 6.0 are based on this single detection. Section 5.0, Figure 1 illustrates the average tritium detections for the last 10 years. DOE-SR did not detect tritium in any of 32 milk samples collected for 2014. Radionuclide contributions to milk may come from SRS, other nearby nuclear facilities, and legacy contamination from the cold war period (CDC 2001).

#### 10.2.2 Gamma-Emitting Radionuclides Results

SCDHEC analyzed for gamma-emitting radionuclides (K-40, I-131, Cs-137, and Co-60) in 16 milk samples collected in 2014. All analytical results for these radionuclides were below the sample Minimum Detectable Activity (MDA), and can be found in Appendix A – ESOP Data. These results are consistent with past gamma results and no summary statistics were calculated for these radionuclides due to a lack of numerical data. DOE-SR had one detection of the gamma-emitting radionuclide Cs-137 out of 32 samples collected in 2014. The amount detected was 3.95 pCi/L and occurred in a sample from a Georgia dairy (SRNS 2015).

#### 10.2.3 Strontium-89/90 Results

Six out of 16 SCDHEC milk samples collected in 2014 exhibited strontium activity above the MDA, including a detection of 0.711 pCi/L in the background sample. The range for these detections was 0.483 pCi/L to 0.943 pCi/L. The minimum detection came from a perimeter location in Govan, SC, and the maximum detection from the background location in Denmark, SC. The average for detections at all locations was 0.648 ( $\pm$  0.123) pCi/L with a median of 0.662 pCi/L for the year (Section 6.0). Section 5.0, Figure 2 shows the trend for SCDHEC strontium detections for the last 10 years. All strontium averages have been below the U. S. Environmental Protection Agency's established minimum contaminant level (MCL) of 8 pCi/L for Sr-90 since testing initiated in 1998 (USEPA 2002d). DOE-SR detected Sr-89/90 in three of 32 samples collected in 2014. All of these detections occurred in samples from SC dairies. The average activity for all detections was 0.551 pCi/L. The highest detection (maximum) was 1.23 pCi/L (SRNS 2015). Summary statistics for perimeter and background locations are in Section 6.0.

### 10.3.0 CONCLUSIONS AND RECOMMENDATIONS

DOE-SR uses all analytical results to compute averages, including results below the Minimum Detectable Concentration (MDC), which is based on the analysis method and comparable to SCDHEC's MDA and LLD. For a more conservative approach, SCDHEC uses only results above the MDA or LLD to compute averages in order ensure that DOE-SR analysis methods are sufficient. This does not affect the general data trend; however, numeric statistics may diverge significantly. Consequently, direct dairy milk analytical data comparisons between SCDHEC and DOE-SR were not conducted.

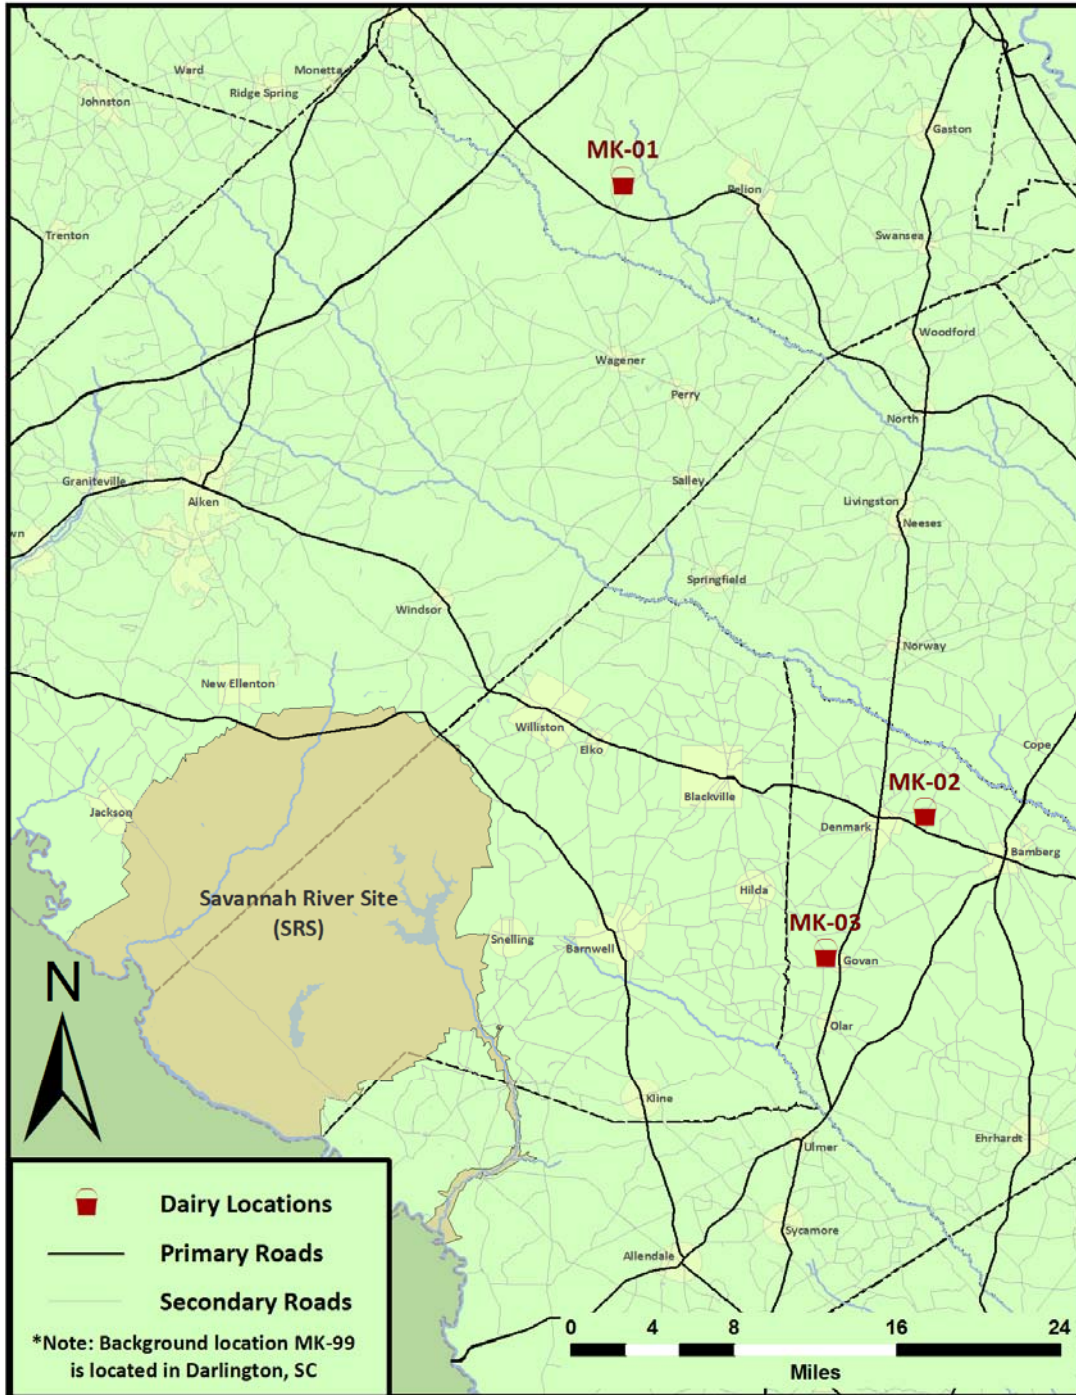

Tritium was detected in samples from 2014. As shown in Section 5.0, Figure 1, tritium detections, while rising, slightly are still well below the USEPA drinking water MCL of 20,000 pCi/L for tritium and are not a concern. Gamma results also continue a trend of non-detections since 2004, with the exception of the I-131 perturbation in 2011. Samples collected after the 2011 occurrence show that I-131 returned to the typically expected results and has not been detected since. The statistical analysis shows that Sr-89/90 concentrations in SRS perimeter samples were slightly less than the concentration in background samples.

A large portion of the radiological activity observed in milk samples can be attributed to fallout from past nuclear testing (Kathren 1984). Also, radionuclides within soil and plants can potentially be redistributed as a result of farming practices and prescribed burns. SCDHEC will continue to monitor tritium, gamma-emitting radionuclides, and strontium in milk to ensure the safety of milk consumption by the public.

The dairies in South Carolina's ESOP study area and background locations appear to be stable with no indication of closing in the foreseeable future. ESOP will continue to seek opportunities to add additional dairies to the sampling program for better coverage of the study area.

### Radiological Monitoring Locations for Dairy Milk

10.5.0 Tables and Figures

Radiological Monitoring of Dairy Milk Figures

Figure 1. Tritium Detection Averages in SCDHEC Milk, 2005-2014

Notes:

1. Average detections are well below the USEPA MCL of 20,000 pCi/L for drinking water.
2. No detections above the LLD were observed in 2005, 2007, 2009, 2010, 2011 and 2012.
3. Some averages may be based on a single detection.
4. The number of dairies may vary from year to year due to the fluctuating number of dairies.

Tables and Figures

Radiological Monitoring of Dairy Milk Figures

Figure 2. Strontium-89/90 Detection Averages, 2005-2014

Notes:

1. Average detections are below the USEPA MCL of 8.0 pCi/L for drinking water.
2. Background samples for 2008 and 2009 were <MDA.
3. Some averages may be based on a single detection.
4. The number of dairies may vary from year to year due to the fluctuating number of dairies.

Aiken, SC 29801

South Carolina Department of Health  
and Environmental Control

### 11.1.0 PROJECT SUMMARY

The South Carolina Department of Health and Environmental Control (SCDHEC) Environmental Surveillance and Oversight Program (ESOP) conducts non-regulatory, independent monitoring and surveillance of fish to determine the magnitude, extent, and trend levels for radionuclides and selected metals.

Largemouth bass (*Micropterus salmoides*) and channel catfish (*Ictalurus punctatus*) were collected from nine sample stations on the Savannah River and a background station established on the Combahee River between Beaufort and Colleton counties. Studies have shown these species bioaccumulate measurable amounts of radionuclides. Stations sampled in 2014 are shown in Map. Section 4.0, and station descriptions can be found in the Monitoring of Fish in the Savannah River Quality Assurance Project Plan, (SCDHEC 1999-2015:2011b).

Fish were collected using boat-mounted electrofishing equipment. Samples were collected at four stations where creeks from the Savannah River Site (SRS) meet the Savannah River: Upper Three Runs Creek (SV-2011), Fourmile Branch (SV-2015), Steel Creek (SV-2017), and Lower Three Runs Creek (SV-2020). Samples were also collected from the background station (MD-119), one Savannah River station upstream of SRS, New Savannah Bluff Lock and Dam (NSBLD SV-2028), and four stations downstream of SRS (Highway 301 SV-118, and Highway 17 saltwater SV-2091). All of these stations are accessible to the public. Fish collections were conducted from May through September of 2014. Five largemouth bass and channel catfish were collected from all Savannah River stations and the Combahee River background site. Five red drum and five sea trout were collected from the saltwater station. A portion of the edible fillets from each fish was analyzed for mercury and selected metals. The remainder of the fillets for each species was combined into homogeneous composites and analyzed for gamma-emitting isotopes and tritium. Non-edible composites consisting of spine, ribs, and tails were analyzed for strontium. Detailed procedures can be found in the Quality Assurance Project Plan (SCDHEC 1999-2015:2011b).

Only the background station on the Combahee River did not produce a sample with detectable tritium activity in 2014. All stations adjacent and downstream of SRS exhibited detectable tritium activity in 2014. Two stations did not exhibit Cesium-137 (Cs-137) activity: Highway 301 and the Combahee River. Activities of strontium-89,90 (Sr-89,90) were reported from all stations.

The Department of Energy-Savannah River (DOE-SR) also conducts fish monitoring to assess the environmental effects of current and historical releases of radionuclides. SCDHEC data were compared to DOE-SR reported results. Although there are differences between reported values, the data is consistent with historically reported data. In the past, samples have been collected and split between SCDHEC and DOE-SR for analyses, and no great variations in the data results were found. This would potentially rule out methodology differences and substantiate that differences result from the variability in samples analyzed by the two programs.

### 11.2.0 RESULTS AND DISCUSSION

A total of 76 fish were collected. Thirty-two composites were processed in 2014. The SCDHEC Midlands EQC Region-Aiken's tritium laboratory analyzed aliquots from all edible samples.

Edible samples were sent to the SCDHEC Radiological Environmental Monitoring Division in Columbia, South Carolina for radiological analysis of gamma-emitting radionuclides. The non-edible bone portions samples were sent to Eberline Services for strontium analysis. Graphic presentations of 2014 and 2010-2014 activity levels of tritium, Cs-137, and Sr-89,90 are reported in Section 5.0. Summary statistics are presented in Section 6.0. All data results will be presented in Appendix A - ESOP Data. Tritium results represent the activity level in the water distilled from the fish tissue. Cesium and strontium results represent the activity level in the wet sample itself. A more in-depth understanding on how these radionuclides may impact human health can be found in the 2014 Critical Pathway Dose Report.

### 11.2.1 Tritium Results

Activity levels of tritium were analyzed in 16 edible composites. All six freshwater stations exhibited detectable tritium activity in 2014 (Section 5.0, Figure 1a). The saltwater sampling station (SV-2091) produced detections in red drum and sea trout samples. The Combahee River background station did not produce tritium activity.

Five of six bass composites from the Savannah River exhibited detectable tritium activity, with an average of 593 ( $\pm$  450) picocuries/liter (pCi/L). The composite from the Steel Creel station (SV-2017) had the highest reported tritium activity, 1280 pCi/L. Four of the six Savannah River channel catfish samples exhibited tritium activity, with an average of 3018 ( $\pm$  5003) pCi/L. The highest tritium level observed in the catfish composites, 10,500 pCi/L, was from Steel Creek.

The 2014 data are generally similar to SCDHEC historically reported data (Section 5.0, Figures 1b and 1c; SCDHEC 2011). Although results can be quite variable between years, tritium levels tend to be highest at the stations adjacent to SRS (creek mouth stations) and decrease with distance downstream. Tritium has been detected upstream of SRS only occasionally, and at low levels.

### 11.2.2 Gamma Results

Activity levels of Cs-137 were analyzed in 16 edible portions of bass, catfish, red drum, and spotted sea trout composites. The Lower Three Runs, Hwy. 301 and the Hwy. 17 saltwater stations did not exhibit Cs-137 activity in any sample.

Three of six edible bass composites from the Upper Three Runs, Fourmile Branch, and the Steel Creek Savannah River stations exhibited detectable levels of Cs-137 ranging from 0.04 to 0.09 pCi/g with an average of 0.06 ( $\pm$  0.03) pCi/g for Cs-137. (Section 5.0, Figure 2a).

Four of six edible catfish composites from the NSBLD, Fourmile Branch, Steel Creek, and the Lower Three Runs Savannah River stations exhibited a detectable level of Cs-137. Ranging from 0.03 to 0.08 pCi/g, with an average of 0.06 ( $\pm$  0.02) pCi/g (Section 5.0, Figure 2a).

Cs-137 was detected in the catfish composite from the Combahee River background station. The catfish composite had a detectable level of 0.052 pCi/g.

### 11.2.3 Strontium Results

The 16 non-edible bone composites were analyzed for Sr-89,90. All stations produced detectable strontium activity, including the background station (Section 5.0, Figure 3a). Sr-89,90 levels reported are for wet results, from analysis of whole fish composites. Averages noted below are for Savannah River freshwater species only, excluding the Combahee River station.

Levels of Sr-89,90 in bass ranged from 0.06 to 0.25 pCi/g with an average of 0.14 ( $\pm$  0.06) pCi/g. Strontium levels in catfish samples ranged from 0.06 to 0.14 pCi/g with an average of 0.10 ( $\pm$  0.03) pCi/g.

Section 5.0, Figures 3b and 3c show historically reported SCDHEC data for Sr-89,90 (SCDHEC 1999-2015: 2011). The data from 2010-2014 represents calculated wet results using a dry/wet conversion ratio from the actual dry analyses. In 2010 data was reported as wet results by the contract laboratory that year.

### 11.2.4 Mercury and Metals Analyses

In 2014, a total of 16 composites were analyzed. The metals (antimony, arsenic, cadmium, and manganese) were selected for concerns from consumption and analysis for direct comparison to DOE-SR data. Samples were also analyzed for chromium, copper, lead, nickel, and zinc. Although small amounts of mercury were released to the SRS environment from site operations, the majority of mercury contamination is a result of atmospheric fallout from coal-burning power plants. (USEPA 2010b). Mercury was detected in fish (primarily bass) from all stations. Composites from the background station on the Combahee River exhibited detectable mercury only in bass. Mercury was detected in bass composite samples from all six Savannah River stations, ranging from 0.15 to 0.85 milligrams per kilogram (mg/kg), with an average of 0.49 ( $\pm$  0.26) mg/kg (Section 5.0, Figure 4). Mercury was detected in catfish from three of the six Savannah River locations, ranging from 0.12 to 0.22 mg/kg, with an average of 0.18 ( $\pm$  0.05) mg/kg (Section 5.0, Figure 4). The following metals were not detected in any samples in 2014: arsenic, antimony, cadmium, and lead. Manganese was detected in eight composites. Nickel and Chromium was detected in three composites. Copper and Zinc was detected in all 16 composites analyzed. Mercury was the only metal detected by both programs.

### 11.2.5 SCDHEC and DOE-SR Data Comparison

SCDHEC bass and catfish data collected for this project in 2014 were compared to DOE-SR reported data (SRNS 2015). Data comparison summaries are located in Section 6.0. One difference between the two programs is that ESOP analyzes one composite from each species for each station, whereas the DOE-SR program analyzes three composites per station. Therefore, a single composite for an ESOP station was compared to the average of the three DOE-SR composites reported. Differences in averages of DOE-SR and ESOP data could be attributed to the fact that DOE-SR uses results below the MDC when calculating averages while ESOP only uses detects.

ESOP largemouth bass samples from five stations and DOE-SR bass samples from three stations exhibited tritium activity. ESOP and DOE-SR detected tritium in catfish samples from four stations. ESOP largemouth bass samples from three stations and DOE-SR bass samples from five stations exhibited Cs-137 activity. Cesium-137 results for edible bass and catfish from ESOP and

DOE-SR were less than 1.00 pCi/g. Strontium-89, 90 was detected at all stations sampled by both programs. (SRNS 2015).

### **11.3.0 CONCLUSIONS AND RECOMMENDATIONS**

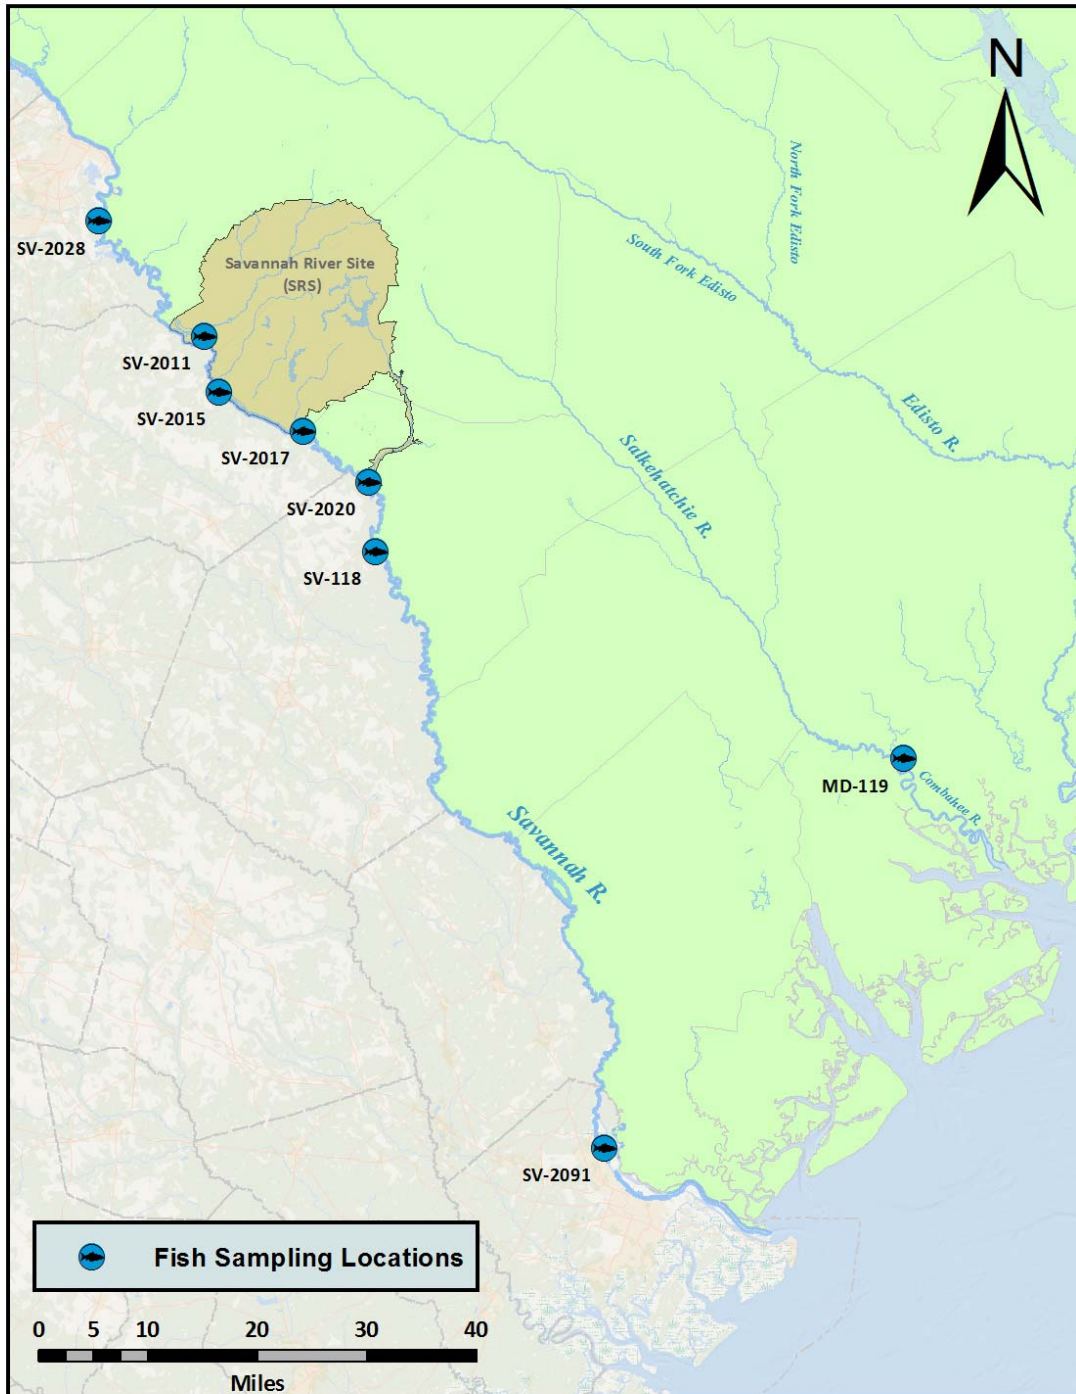

A review of SCDHEC data indicates that DOE-SR operations have impacted fish. Higher levels of radionuclides are found in Savannah River fish collected adjacent to and downstream of SRS compared to upstream.

Independent monitoring of radionuclide levels in Savannah River fish will continue along with evaluating the DOE-SR Radiological Fish Monitoring Program. Continued monitoring will provide a better understanding of actual radionuclide, their extent, and trends. This data will allow SCDHEC to better advise, inform, and protect those people at risk. Although Cs-137 and Sr-89,90 are found in some Savannah River fish, the levels are low and have decreased over time. If the public follows the SCDHEC mercury advisories for consumption of fish from the river, the health risk from these radioactive elements is very low (SCDHEC 1999-2015: 2010). Data comparison will also be part of the further evaluation of the DOE-SR program. This independent evaluation will provide credibility and confidence in the DOE-SR data and its uses.

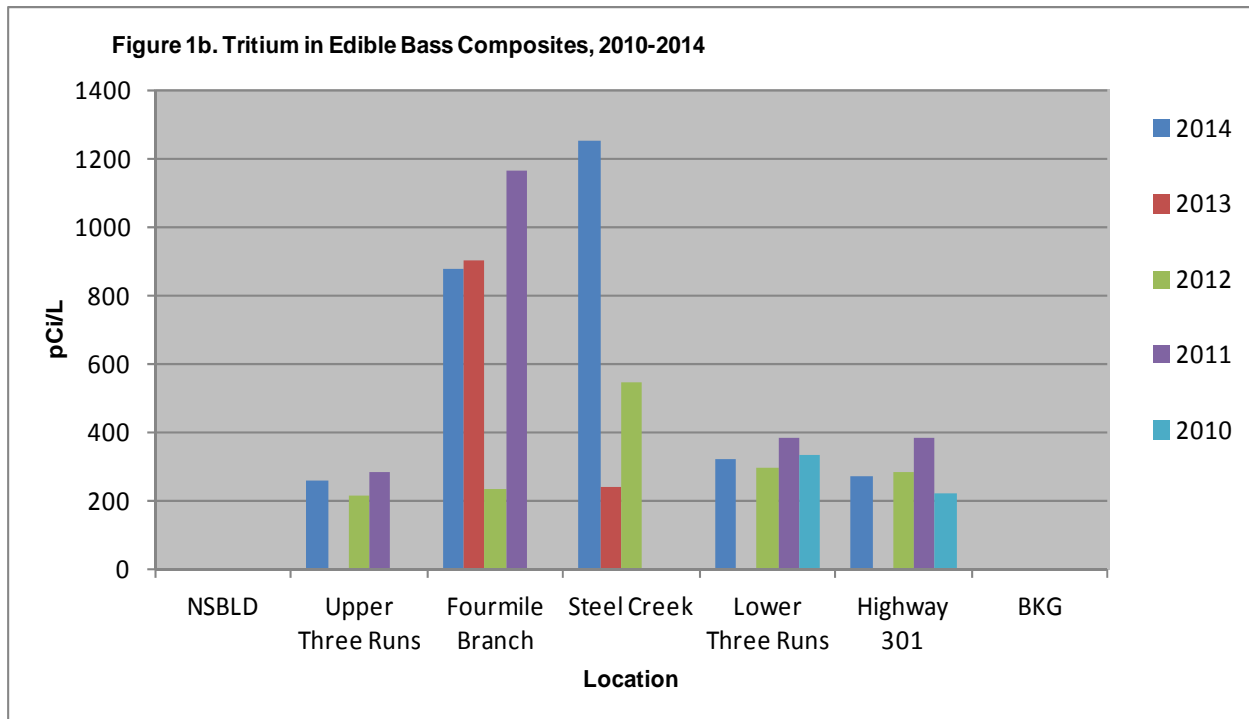

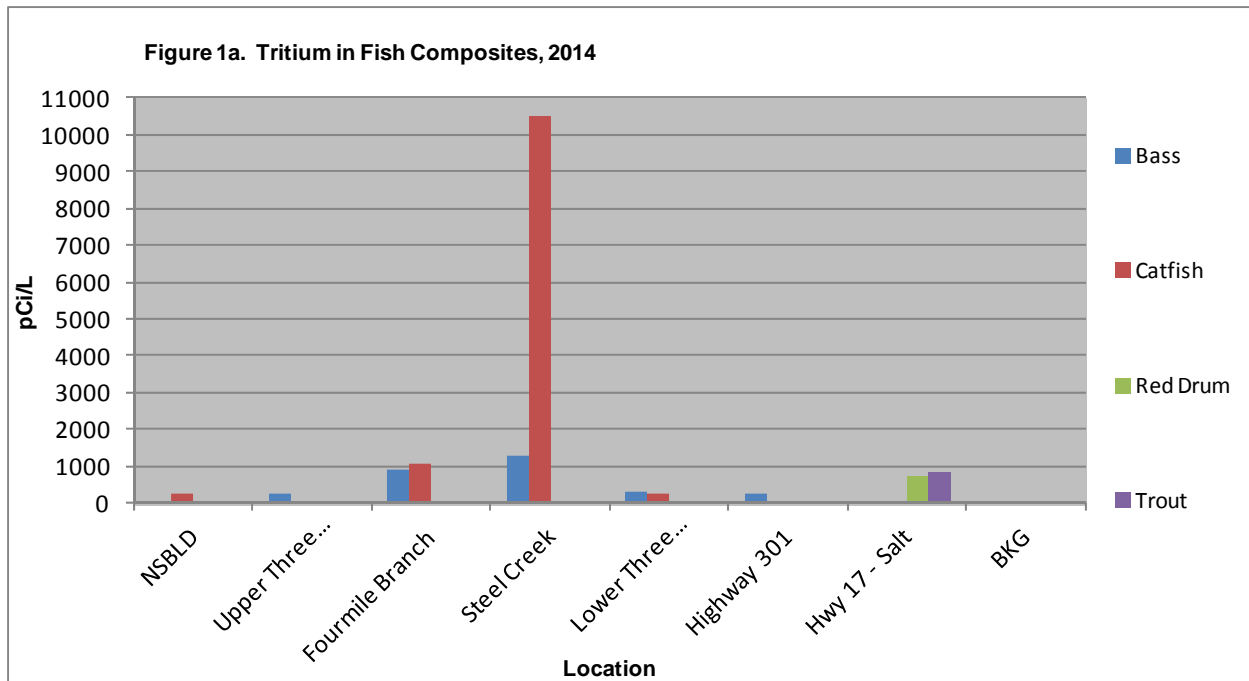

Future analyses of the target species will continue to include mercury and selected metals. This will augment the existing data on Savannah River fish, provide information for human health assessment, and provide another basis for comparison of results with DOE-SR data.

### 12.1.0 PROJECT SUMMARY

The South Carolina Department of Health and Environmental Control (SCDHEC) Environmental Surveillance and Oversight Program (ESOP) conducts independent non-regulatory oversight of game animal monitoring activities within a five-mile study area around the Savannah River Site (SRS). The game animal project addresses concerns of potentially contaminated white-tailed deer and feral hogs migrating off the SRS, and can provide valuable information concerning the potential off-site exposure to cesium-137 (Cs-137) by analyzing samples collected off-site. White-tailed deer and feral hogs have shown the highest potential of the mammalian species for a human exposure pathway from Cs-137 (Haselow 1991). SCDHEC analyzed muscle tissue collected in 2014 for Cs-137 from 31 deer and four hogs collected from area hunters via hunting clubs, plantations, and Crackerneck Wildlife Management Area within a five-mile study area adjacent to the SRS (Section 4.0, Map). Additionally, 10 deer tissue samples were collected and analyzed from a background location 85 miles southeast of the SRS in Beaufort County, South Carolina. Sample size, location, and collection dates were dependent on the participating hunters.

The Department of Energy-Savannah River (DOE-SR) has annual hunts open to members of the general public to control the site's deer and feral hog population and to reduce animal/vehicle accidents. Before any animal is released to a hunter, SRS personnel monitor Cs-137 levels for exposure limit considerations to ensure established administrative dose limits are not exceeded. During the 2014 annual on-site hunts, DOE-SR split 87 samples with ESOP for a analytical data comparison.

DOE-SR does not collect game animal samples within the SCDHEC study area, and off-site hunter doses are based on DOE-SR models. Therefore, no direct comparisons could be made between SCDHEC and DOE-SR data. The ESOP Critical Pathway Dose report addresses dose based on collected samples and is compared to DOE-SR modeled dose for off-site hunters.

White-tailed deer and feral hogs have access to a number of contaminated areas on and off the SRS and are a vector for the redistribution of contaminants (primarily Cs-137) to off-site locations. A five-mile study area was established based on a typical white-tailed deer upper limit home range to ensure that potentially contaminated deer residing at or near the SRS boundary would be included in the sample set. Consumption of these wildlife species can result in the transfer of contaminants to humans. Cesium-137 is of concern because of the 30 year half-life, its availability to game animals, and associated health risk to humans (Haselow 1991).

Cesium-137 is readily incorporated into the human body because of its similarity to potassium-40 (K-40) in physiological processes (Davis 1963). Cesium-137 concentrates in animal skeletal muscles that are selectively consumed by hunters (Brisbin et al. 1975). Cesium-137 emits both beta and gamma radiation, contributing to both internal and external radiation exposure, which may be associated with gastrointestinal, genetic, hematopoietic, and central nervous system damage (Bond et al. 1965). Because of these concerns, Cs-137 will be the focus isotope of this report.

## 12.2.0 RESULTS AND DISCUSSION

### 12.2.1 Cesium-137

Cesium-137 and the naturally occurring isotopes K-40, lead 212 (Pb-212), and lead-214 (Pb-214) were the only isotopes detected in game samples collected in 2014. Naturally occurring isotopes will not be discussed in this report. Cesium-137 concentrations from deer collected in the SRS perimeter study area are shown in (Section 5.0, Figure 1). Analytical results are listed in Appendix A – ESOP Data.

Cesium-137 activities from the 31 SCDHEC perimeter deer samples ranged from < Minimum Detectible Activity (MDA) to 4.08 picocuries per gram (pCi/g), with an average of 1.06 ( $\pm$  0.94) pCi/g (Section 6.0). Cesium-137 activities from the four SCDHEC perimeter hog samples ranged from 0.47 to 2.51 pCi/g with an average of 1.58 ( $\pm$  0.98) pCi/g (Section 6.0). Results from the 10 background deer samples ranged from 0.16 pCi/g to 0.63 pCi/g, with an average of 0.41 ( $\pm$  0.15) pCi/g.

### 12.2.2 SCDHEC and DOE-SR Cesium-137 Data Comparison

DOE-SR reported an approximate field measurement range of 1.00 pCi/g to 8.37 pCi/g with a field gross average of 1.29 pCi/g from 587 deer and a range of 1.00 pCi/g to 3.84 pCi/g with an field gross average of 1.32 pCi/g from 135 feral hogs harvested on the SRS in 2014 (SRNS 2015). Average perimeter, background, and DOE-SR on-site Cs-137 levels for the past five years (Section 6.0) are indicated in Section 5.0, Figure 2. The five-year Cs-137 averages between SCDHEC and DOE-SR may differ for various reasons. The DOE-SR data is acquired in the field by using a portable sodium iodide detector while SCDHEC data are analytical results. Also, the SCDHEC data presents a challenge for direct comparisons to DOE-SR data because the perimeter area is heavily baited. Therefore, the uptake of Cs-137 by these animals will be reduced based on the increased K-40 levels in the corn from fertilizers (Heckman 1992).

During the 2014 annual on-site hunts, DOE-SR split eighty deer and seven hog samples with ESOP for an analytical data comparison. DOE-SR cesium-137 data activities for ranged from 0.17 pCi/g to 7.76 pCi/g with an average of 1.52 pCi/g for deer and 1.12 pCi/g for hogs. ESOP Cesium-137 data activities ranged from 0.23 pCi/g to 8.83 pCi/g with an average of 1.67 pCi/g for deer and ranged from 0.36 pCi/g to 5.04 pCi/g with an average of 1.29 pCi/g for hogs..

## 12.3.0 CONCLUSIONS AND RECOMMENDATIONS

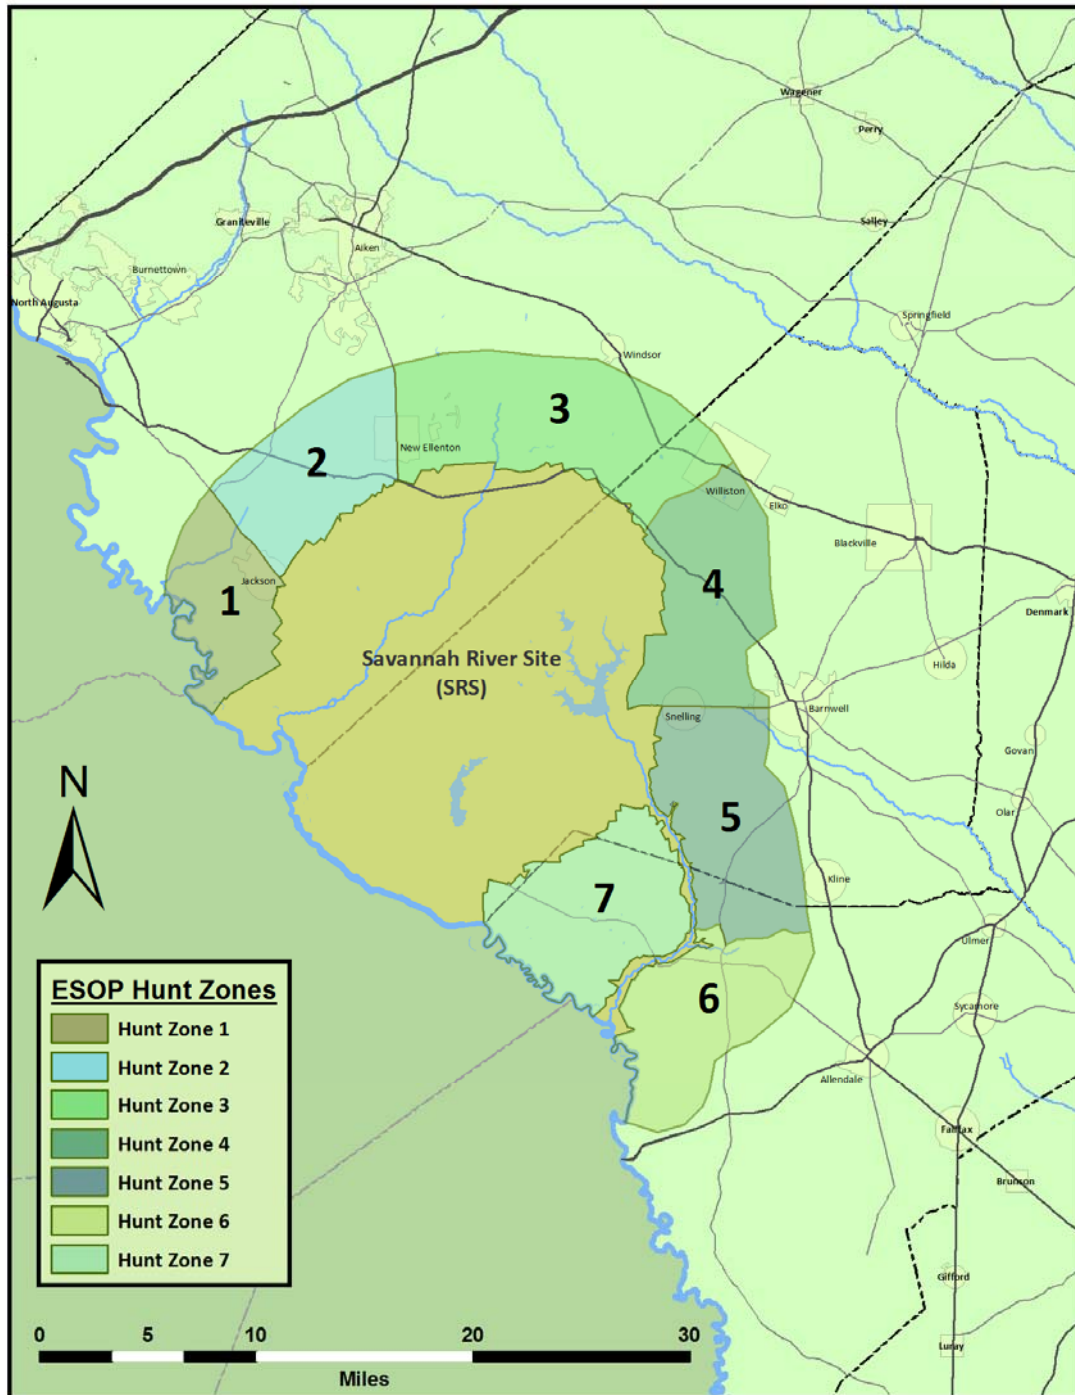

Historic SRS operations released known Cs-137 contamination to Steel Creek, Par Pond, Lower Three Runs, their floodplains, and the Savannah River swamp (Till et al 2001), all of which impact hunt zones four, five, six, and seven (Section 4.0, Map). Although a portion of Cs-137 was deposited on the SRS from site operations, levels found in the study area and background location are likely results of above ground nuclear weapons testing (Haselow 1991). DOE-SR does not collect game animal samples within the SCDHEC study area, and off-site hunter doses are based on DOE-SR models from animals collected on the SRS.

Age, sex, body weight, soil type, diet, and collection location may affect the Cs-137 activities found in white-tailed deer and hogs (Haselow 1991). The differences in average activities (Section 5.0, Figure 2) are possibly a combination of one or more of the above factors. A hunter consuming deer from the SRS, the study area, or background locations would most likely ingest a portion of the activity associated with these animals. Refer to the ESOP Critical Pathway Dose report for a better understanding of the contamination found in game versus other food sources.

SCDHEC will continue to monitor Cs-137 levels in deer and hogs within the established study area and background locations to assess trends and human health impacts. SCDHEC will continue to pursue new hunters within the five-mile study area to ensure adequate sample numbers can be achieved each year. SCDHEC will also put additional efforts into trapping wild hogs within the study area.

### 13.1.0 PROJECT SUMMARY

The South Carolina Department of Health and Environmental Control (SCDHEC) Environmental Surveillance and Oversight Program (ESOP) monitors the Savannah River Site (SRS) and adjacent areas under an Agreement in Principle with the United States Department of Energy (USDOE). Atmospheric pathway and liquid pathway discharges from SRS were monitored by the Department of Energy – Savannah River (DOE-SR) contractor Savannah River Nuclear Solutions (SRNS) Environmental Monitoring Section (EMS). DOE-SR and SCDHEC used data from their monitoring activities to calculate the potential radiation dose in millirem (mrem) to the surrounding public.

SCDHEC implemented a Radionuclide Dose Calculation Project/Critical Pathway Project to calculate the potential exposure or dose to the public within 50-miles of an SRS center-point. This study area was chosen for comparison to the DOE-SR 80-km (50-mile) radius dose results. Individual project managers chose differing sample locations/schemes within this study area to establish trends in media radionuclide concentrations. Radionuclide dose potential exposure to the public was calculated by SCDHEC from radionuclide concentration activities found in various media that may impact the public (Section 5.0).

A comparison of similar SCDHEC and DOE-SR media resulted in an evaluation of both programs based on media potential exposure in mrem (Section 2.0). Summary statistics (Section 6.0), and figures (Section 4.0) illustrate the trends and central tendencies in the critical pathway potential dose exposures. The critical pathway dose is calculated (Section 4.0) on average exposed individual (AEI) and maximum exposed individual (MEI) bases which are summarized in Section 4.0, Table 1.

It is important for the reader to note the differences in DOE-SR and SCDHEC critical pathway dose estimations. Some DOE-SR dose calculations use modeling based on estimates of known releases from SRS facilities within the report year while SCDHEC annual dose estimates are based solely on field sample results.

Also, SCDHEC calculates an upper bound of potential dose, the MEI. This estimate is based on the single highest maximum dose per radionuclide per media that may result in exposure throughout the year as if that maximum is somehow stored and used throughout the year. A one time filling of a water cistern with Savannah River water for consumption during a MEI dose event is an example of storage dose for an ingestion potential MEI. The MEI calculation also represents an upper bound estimate of potential accumulated exposure that may not have been detected.

MEI data is assigned to the maximally exposed individual, conceptualized by SCDHEC as a survivalist who is exposed to all media maximums as if the MEI exposure occurred throughout the entire year. An alternate possibility existed that all potential exposure was not detected, but was allowed for by adding the ESOP MEI calculation and any additional DOE-SR release estimates greater than the SCDHEC sample estimates (Section 4.0, Tables 1 and 3). The health of the public and environment are protected when all of these estimates are below established protective dose standards/limits for the various radionuclides and pathways of exposure. The DOE Order 5400.5 (USDOE 1993) dose limits to yearly releases do not apply to accumulated dose in environmental samples. However, they do provide a comparison basis that

illustrates environmentally accumulated dose totals over several years are less than the yearly DOE-SR release limits (10 mrem air, 4 mrem liquid, and 100 mrem total for all radionuclides released in a given year; SRNS 2015).

The 2014 media calculations were represented on an AEI basis (average potential dose if exposed to all media sampled) and on a MEI (upper bound) basis of potential exposure per media, per radionuclide (Section 4.0, Table 1). The MEI (11.995 mrem in 2014) basis provides a radiation exposure limit based on the single highest potential dose in media. An individual's average exposure should be less than or closer to the AEI media total (3.933 mrem in 2014). Individual exposures may be far less than the AEI total due to temporal factors and the lack of contact by an individual with all media collected.

For calendar year 2014, new consumption rates, used in calculation of dose from sample concentrations, were used for some media (SRNS 2015). Other consumption rates that were unavailable in the SRS environmental report were obtained from the Exposure Factors Handbook: 2011 Edition (United States Environmental Protection Agency (USEPA) 2011) and Wages and Benefits for Farm Employees-Results of a 2011 Iowa Survey (Iowa State University 2012).

The SCDHEC MEI plus DOE-SR total (37.2 mrem) is based on the total of the highest possible exposure from environmental media (MEI column, Section 4.0, Table 1), plus other dose modeled or detected by DOE-SR that has the potential to impact the public (Section 4.0, Table 3). For example, the SCDHEC dose estimates are only from dose detected offsite and the addition of onsite DOE-SR dose estimates includes most of the total potential dose from public exposure sources.

The 2014 MEI dose of 11.995 mrem as determined by SCDHEC was primarily due to cesium-137 (Cs-137; Section 4.0, Table 1). Cs-137 accounted for 97.76 percent of the AEI dose contribution and 91.18 percent of the MEI dose contribution during 2014. Any correlation between SCDHEC dose data and DOE-SR dose data would be due to the dominant radionuclide dose contributors Cs-137, strontium-90 (Sr-90), and tritium (H-3) to exposure via comparable media.

The following comparisons to DOE-SR annual release limits are not explicitly applicable since dose found in media represents many years of dose accumulation, but the comparison is made to show that even the accumulated dose in the environment is less than the annual DOE-SR standard release limits for the air, liquid, and all-pathway categories (SRNS 2015). The SCDHEC 2014 estimate for all-sources AEI exposures from the combined atmospheric and liquid pathways, 3.933 mrem, and the liquid pathway, 0.162 mrem, were beneath the respective 10 mrem and 4 mrem annual DOE-SR release limits (Section 4.0, Table 2; SRNS 2015). An upper bound 2014 MEI (excluding naturally occurring radioactive material (NORM) detections) accumulated dose potential (37.2 mrem) calculated from the combined data of DOE-SR and SCDHEC was also strictly not applicable to the 100-mrem DOE-SR annual release limit to the public (Section 4.0, Table 3; SRNS 2015).

### 13.2.0 Results and Discussion

The SCDHEC MEI is a hypothetical subsistence and survivalist type of individual who resides in the downriver swamp area below all SRS contributions to the Savannah River, visits the entire 50-mile perimeter study area, and receives the MEI dose based on the single highest detection per radionuclide per media detected in the environment. The 2014 data and dose results are discussed under the following headings in this section: 2014 AEI and MEI Dose, 2014 Added Dose Basis, Critical Pathways 2014 Summary, DOE-SR and SCDHEC 2014 Comparisons, and the Dose Critique. The statistical summary covers the 2005-2014 period, whereas other headings discuss only 2014 data. Not all media were collected throughout this summary period (2005-2014). See Section 6.0, Table 2 for the total years of collection for the individual media.

The critical pathways were analyzed both on a mrem basis and percentage of dose basis (Section 6.0, Table 1). Percentages denote relative importance, whereas mrem denotes potential exposure levels. The dose critique attempts to indicate the limits of this dose estimate and why any DOE-SR and SCDHEC estimates may or may not be similar.

#### 13.2.1 2014 AEI and MEI Dose

The basis for dose calculations is not limited to any particular pathway(s) of dose exposure based on lifestyle or media encountered, but is simply a tabulation of all detected dose found in all media sampled regardless of applicability to an individual. Table 1 in Section 4.0 summarizes all SCDHEC detections by media on an AEI and MEI detection basis. Background readings are not subtracted before dose calculations are performed.

The AEI dose is a conservative estimate based on consumption rates (CRs), represented by the CR column in the data tables, and average dose per media (Section 5.0, Data). In 2014 the calculated AEI dose was 3.933 mrem (Section 4.0, Table 1), with 3.884 mrem from food dose. If wild game is not consumed, the AEI dose falls to 0.213 mrem. The AEI dose skews high, as only detections are used in the dose calculations. For a typical person in the study area, the dose they receive will be considerably lower than the AEI dose.

In 2014 the total calculated MEI dose was 11.995 mrem, of which 11.362 mrem was attributable to food consumption. If wild game is not consumed, the MEI dose falls to 2.258 mrem. The MEI basis column uses the single highest detection for a media radionuclide and calculates dose as if the high dose occurrence was somehow stored and the exposure continued throughout the year (Section 5.0). If the individual did not store the media at the location, date, and time of SCDHEC sample collection, and achieve a full year's exposure to that media, then the MEI estimate represents a sizable overestimate (upper bound based on data extreme).

Only speciated doses for specific radionuclides were included in the estimated doses for 2014. The use of detections only in determining AEI dose per radionuclide per media, the calculation of dose based on the MEI detection for each radionuclide/media, and conservative consumption references provided a protective dose estimate. Each media radionuclide dose, excluding NORM, was considered as part of a different critical pathway with contributions through the inhalation, ingestion, and direct exposure routes.

The SCDHEC MEI grand total (37.2 mrem) that includes added dose from DOE-SR (25.3 mrem) was based on the total of all SCDHEC MEI (11.995 mrem) exposure estimates plus any

additional exposure estimates by DOE-SR (Section 4.0, Table 3). This combined onsite and offsite MEI dose was an improbable dose based on maximums that could potentially be consumed by only one individual. All other individuals would receive the AEI dose or less. Most of this dose came from wild game consumption. It should be noted that the DOE-SR onsite hunter dose for 2014 was based on a much higher consumption rate for wild game relative to 2013.

The MEI dose can be received by only one individual, since that individual had to consume the specific dose basis animals. Two elevated dose bases (AEI and MEI) were used because they were measured and protective without the inclusion of screening value assumptions for alpha and beta. The assumption of all alpha as plutonium-239 (Pu-239) and all beta as strontium-90 may double the calculated dose without evidence for that assumption in speciated data. These dose assignments were discontinued in 2008 and replaced by calculating an MEI dose potential from the single highest detection per radionuclide per media.

### **13.2.2 2014 Added Dose Basis**

Section 4.0, Table 3.0 includes data from Table 6-5 of the SRS Environmental Report that can be added to give a total combined SCDHEC plus DOE-SR onsite and offsite dose potential of 37.2 mrem for the upper bound MEI estimate (SRNS 2015). This addition of dose detections other than SCDHEC detections from other environmental programs helped to extend the MEI potential dose limit on a definable basis. The main contributors to this combined onsite and offsite maximum dose estimate were the DOE-SR onsite hunter dose (22.3 mrem), and the SCDHEC offsite wild game dose (9.7 mrem). The onsite DOE-SR hunter would have to consume the highest dose game animals harvested onsite in 2014, and the same hunter would also have to receive and consume all of the highest dose offsite SCDHEC MEI game animals to achieve just the hunter portion of the combined onsite and offsite dose potential. Thus, the achievement of this maximum dose estimate by the MEI is highly unlikely.

### **13.2.3 Critical Pathways 2014 Summary**

All SCDHEC dose detections occurred in the atmospheric and liquid pathways from the food ingestion, air and dust inhalation, direct exposure, public water supply ingestion, and the nonpotable drinking water ingestion routes (in this report, nonpotable drinking water is surface water or collected rainwater that has been treated in small batches by an individual through boiling or the addition of iodine). Percentage comparisons of critical pathways in 2014 denoted their relative importance to overall dose exposure (Section 4.0, Table 2). The 2005-2014 Statistics Summary Section 6.0 covers the overall media trends. The AEI data represented the typical yearly dose levels while the MEI data represented the extreme data points, or one time dose extreme, that occurred sometime during the year. The MEI dose was very conservative since it was based on a single high detection per radionuclide per media as if they were stored and constantly used throughout the year.

#### The Atmospheric Pathway 2014 Summary

The SCDHEC 2014 atmospheric pathway contributed dose to the individual through the inhalation of air and resuspended soil, ingestion of food (predominantly from wild game), and the direct exposure and nonpotable drinking water subpathways. Section 4.0, Table 2 illustrates

the dominance of the atmospheric pathway, contributing 95.88 percent of dose, over the liquid pathway, which contributed 4.12 percent of dose in 2014 routes of exposure for the AEI. For the MEI, the percentages were 84.97 percent of dose contributed by the atmospheric pathway and 15.03 percent of dose contributed by the liquid pathway.

Section 4.0, Table 1 and Figures 1 and 2 illustrate that most of the AEI dose exposure in 2014 was due to Cs-137: 3.841 mrem total, in wild game, fish, and soil and sediment. Tritium was the second highest dose exposure in 2014 at 0.091 mrem, and Sr-89/90 third at 0.001 mrem. Cs-137 and tritium were both found in the the atmospheric and the liquid pathways. Sr-89/90 was found in the atmospheric pathway only.

#### The Liquid Pathway 2014 Summary

The SCDHEC 2014 liquid pathway estimated AEI dose to the individual was through the ingestion of fish, groundwater, surface water, public water supplies from the Savannah River, swimming ingestion, inhalation, and direct exposure routes and pathways (Section 4.0, Table 1). Riverbank soil is an example of a media that can impact both atmospheric (through inhalation of resuspended dry sediments) and liquid pathways (through ingestion and direct contact).

The liquid pathway contributions to dose exposure were second to those contributed by the atmospheric pathway. In 2014, the liquid pathway contribution to the AEI was 0.162 mrem, accounting for 4.12 percent of dose. The contribution to the MEI dose was 1.803 mrem, at 15.03 percent. A review of the Section 5.0 data shows Cs-137 to be the primary contributor to dose from fish in the liquid pathway. It must be noted here that Sr-89/90 in fish, which was the primary contributor to the liquid pathway fish dose in 2013 and would be in 2014 if included, is no longer used to calculate a dose, as it primarily accumulates in the bones which are usually discarded rather than eaten.

#### The Food Subpathway 2014 Summary

The food subpathway was covered under the atmospheric and liquid pathways except for these few additional observations. The annual 2014 SCDHEC AEI food subpathway dose order, highest to lowest for averages, was hog, deer, fish, edible vegetation, and milk. Single high detections can occur in any of the game, fish, or wild fungi and vegetation samples, and cause a reversal of the rank order of media in any year.

The 2014 MEI food pathway order was deer, hog, fish, edible vegetation, and milk. Most of this dose was due to Cs-137 in wild game for the AEI and the MEI, at 3.720 mrem and 9.737 mrem respectively. The food pathway contained all detected radionuclides, including Cs-137, Sr-89/90, and tritium, which contributed to dose exposure.

#### **13.2.4 2005-2014 Summary Statistics**

Section 6.0, Table 1 summarizes dose associated with all media on an AEI basis from 2005-2014. The critical pathway basis of comparison for SCDHEC detected dose comes from accumulated releases of radionuclides that were deposited outside of SRS during 2005-2014 and within 50-miles of the SRS center-point. Table 1 illustrates the dominance of the atmospheric pathway dose (72.44 percent) over the liquid pathway (27.56 percent). The food subpathway

(94.60 percent) was the dominant route of exposure for accumulated dose, with the water subpathway being second at 5.01 percent.

Section 4.0, Figures 3, 4, and 5 and Section 6.0, Tables 1 and 2 illustrate the various pathways of dose exposure. The total detected AEI basis critical pathway dose, 3.933 mrem, is just slightly greater than half the 7.00 mrem dose an individual typically receives from living in a brick house for one year (Wahl 2011). Section 4.0, Figures 3, 4, and 5 illustrate the media exposure trends via line graphs.

The predominant source of exposure from 2005-2014 was wild game (ie. Deer and hog). In total it accounted for 12.569 mrem, which amounts to 56.13 percent of the total accumulated AEI exposure (22.394 mrem) during that time period. Following wild game were fish (5.148 mrem; 22.99 percent), fungi (2.112 mrem; 9.43 percent), and edible vegetation (1.132 mrem; 5.05 percent). Furthermore, wild game accounted for 78.56 percent of the accumulated dose from the atmospheric pathway (Section 6.0, Table 1) and 59.33 percent of the food subpathway (Section 6.0, Table 1).

The predominant routes of accumulated exposure for water sources were nonpotable drinking water from the Savannah River (0.407 mrem; Section 6.0, Table 1), public system drinking water from the Savannah River (0.224 mrem), and South Carolina Department of Natural Resources wells, which serve as a proxy for private wells, and also private wells (0.195 mrem). The primary routes for minor sources of accumulated dose were accidental ingestion from swimming (0.058 mrem), direct exposure from farm soil (0.039 mrem), and direct exposure from wading (0.025 mrem). Combined, the water and minor dose subpathways account for only 6.40 percent of accumulated dose.

The Median Yearly Dose column in Section 6, Table 2 represents the midpoints of bodies of data, thus minimizing the influence of extremes. This should provide the most relevant measure of central tendency for environmental media exposure over the 2005-2014 period. The median is still protective because the statistics are based on detections only (Gilbert 1987). The dominant sources of accumulated exposure on an AEI median basis were wild game (5.660 mrem), fish (4.920 mrem), and fungi (2.203 mrem) (Section 6.0, Table 2; Median Yearly Dose accumulated over a ten year period). These three media accounted for 88.27 percent of accumulated AEI dose on a median basis.

The primary contributors to the water sources accumulated AEI dose on a median basis were nonpotable drinking water from the Savannah River (0.320 mrem), public system drinking water from the Savannah River (0.180 mrem), and nonpotable drinking water from rainwater (0.140 mrem; 6.0, Table 2; Median Yearly Dose accumulated over a ten year period). Accidental ingestion from swimming (0.050 mrem), direct exposure from soil (0.010 mrem), and inhalation of air (0.020 mrem) were the primary contributors to the minor sources accumulated AEI dose.

### 13.2.5 DOE-SR and SCDHEC 2014 Comparisons

DOE-SR calculates potential doses to members of the public from atmospheric and liquid releases, as well as from special-case exposure scenarios, on an annual basis (SRNS 2015). These include liquid pathway and air pathway doses, an all-pathway dose, a sportsman dose,

onsite and offsite hunter doses, and an offsite fisherman dose. The DOE-SR dose estimates are analogous to SCDHEC dose estimates as follows, although it must be noted that there are differences between DOE-SR and SCDHEC sampling and dose estimation protocols:

1. The DOE-SR all-pathway dose and the sum of the SCDHEC fish, wading, swimming, public system drinking water from the Savannah River, vegetation, and milk doses – these serve as an estimate of the dose a typical member of the public in the study area, an individual who doesn't consume wild game or gather edible mushrooms, could receive from SRS activities during a given year.
2. The sum of the DOE-SR all-pathway, sportsman, Savannah River swamp hunter, and Savannah River swamp fisherman doses and the SCDHEC MEI – these serve as an upper bound estimate of the dose a survivalist type of individual who consumes fish from the Savannah River and wild game could receive in a given year.

The DOE-SR all-pathway and the SCDHEC Public Scenario basis were the most relevant dose estimates that represent the potential dose exposure for the general public in 2014. The DOE-SR representative person all-pathway dose for 2014 was 0.16 mrem, a decrease from 0.19 mrem in 2013. The sum of the SCDHEC AEI fish, wading, swimming, public system drinking water from the Savannah River, vegetation, and milk doses was 0.17 mrem in 2014. The SCDHEC public scenario dose estimate for 2014 is only 0.17 percent of the DOE all-pathway dose standard of 100 mrem/yr (SRNS 2015).

The sum of the DOE-SR all-pathway, sportsman, Savannah River swamp hunter, and Savannah River swamp fisherman doses was 25.07 mrem in 2014, of which the single largest contributor was the DOE-SR onsite hunter dose, at 18.03 mrem. It must be noted that the DOE-SR dose summations are done for comparison to SCDHEC results and, when combined with SCDHEC results, represent an upper bound worst case scenario of the dose potential that exists on and offsite. This should not be construed as a dose any one individual can receive. The SCDHEC MEI dose estimate for 2014, derived from offsite measurements only, was 11.995 mrem. With the DOE-SR onsite hunter added to the SCDHEC MEI, the total combined dose estimate was 30.03 mrem, or 34.03 mrem when onsite turkey is included.

### 13.2.6 Dose Critique

The median may be a better reference for deciding the true central tendency in environmental data when media sample numbers are relatively large in size and based on detections only (Gilbert 1987). Random sampling in most SCDHEC media revealed that the environmental data detections are asymmetric and skewed to the left (most detections are low and near the origin). The median of the population probably tends to be larger than the true mean. Most sampling resulted in less than minimum detectable activity (<MDA) determinations and were not included in the above SCDHEC statistics, which used detections only. The use of detections only in statistics was protective, and biases the measures of central tendency higher.

The DOE-SR study area shows a gradual downward exposure trend that may be attributable to the shift in SRS' mission from production to cleanup and environmental remediation. All dose was summarized by average, standard deviation, and median. The median may be a better indicator of the central tendency in environmental media dose compared to average dose for

large sample numbers due to:

- 1) the decrease in the central tendency for the bulk of the data without extremes;
- 2) the added conservancy present in selected dose factors;
- 3) the addition of dose based on single highest detections such as hog and deer worst-case game animal consumption;
- 4) the use of “detections only” for statistical analyses when many sample results were less than the detection limit;
- 5) the assignment of the higher dose to dual radionuclide determinations (e.g., the assignment of dose based on Sr-90 when the detection is for Sr-89/90 or total strontium);
- 6) the use of zero mrem as background subtraction for <MDA data averages;
- 7) the influence or potential of false positives;
- 8) and while the median does represent the bulk of the data, the application of statistical methods for eliminating extremes without an assignable cause does not preclude the variation in the natural environment.

The NORM averages and maximums were not included in the dose estimates since this dose was considered to be part of the background dose for the study area. The yearly dose averages were based on SCDHEC detections only and are inflated since most sample results were <MDA. The MDA values are below typical South Carolina background detections and would not add dose to the MEI. The justification for using detections only was to allow for undetected radionuclides and media. The justification for selecting higher source consumption levels was due to the conceptualization of the SCDHEC MEI as a survivalist type who consumed natural media at a greater than typical use rate. The basis for both considerations was to be protective of the public and environment.

The inclusion of alpha and beta assumed dose in the past provided an excessively high dose estimate and was not supported by media radionuclide species detections. The inclusion of calculations based on a single highest maximum detection for each radionuclide/media was a more definable basis for establishing an upper bound rather than the dose assumption of unknown alpha as Pu-239 and unknown beta as Sr-90. This upper bound is not practically achievable by the MEI due to the unlikely exposure to all maximums at a constant rate throughout the year (via storage of media). However, since most of the dose was due to wild-type food (whether animal or plant) consumption containing Cs-137, then a single individual who ate all of the worst case deer, hog, and edible plant and mushrooms could approach the MEI dose if these contaminated media were stored and consumed over the entire year.

The SCDHEC 2007 Critical Pathway Dose Report noted that 38.50 percent of the dose was assigned and represented a potential dose overestimate that may in fact be NORM detections (alpha and beta). Also, only 44.25 percent of the detected dose above background was potentially from SRS, if all NORM potentials were excluded. The SCDHEC dose calculations since then were still protective due to the use of detections only in determining dose, the calculation of a maximum dose for the MEI based on a single maximum detection for each radionuclide/media, and the use of very conservative consumption rates.

The AEI was given prominence as protective for general dose considerations, and the reader should be aware that the AEI dose estimate was conservative or biased high due to the use of detections only for dose calculation. For example, the omission of <MDA assignments from

calculations would raise any calculated number to a higher value. Alternatively, <MDA actually represents an undetermined low number that may be zero or any number up to the given MDA value for that analysis.

All detected dose was assigned either to the AEI or the MEI (Section 4.0, Table 1 and Section 5.0 Data). The SCDHEC MEI was primarily a sportsman scenario because most potential dose was found in game animals and fish. However, the wild edible mushroom and plant consumer potential dose would add significant additional dose to the survivalist. The MEI by definition would consume all maximum activity per radionuclide per media and defined a limit of potential dose based on detections only. This was done since SCDHEC sampling was limited and did not necessarily include the true yearly MEI exposure (due to undetected dose and/or dose accumulations) for the exceptional individual who may receive the MEI dose resident in the 50-mile perimeter study area. Thus, the dose limiting factors were biased high to be protective of the public and the environment, but realistic or limiting in that only measured radionuclides were used in calculations.

Specific radionuclide (speciated) doses were used in the estimated dose for 2014 except for the dose assignments of total strontium as Sr-90. The use of detections only, the calculation of dose based on a single maximum for each radionuclide/media, and high consumption levels, provide an elevated dose basis that is protective without the inclusion of screening value assumptions for alpha and beta. SCDHEC field detection dose accumulations from 2005 through 2014 and DOE-SR yearly releases were not directly comparable and yet the potential MEIs calculated from both programs were similar.

This project used dose instead of risk so that direct comparisons of dose magnitude can be made with similar media data published in the SRS Environmental Reports. DOE-SR modeled radionuclide releases for a particular year were not directly comparable to SCDHEC yearly-detected dose in some media due to bioaccumulation.

### 13.3.0 CONCLUSIONS AND RECOMMENDATIONS

A very conservative estimate by SCDHEC of the average SRS perimeter accumulated dose potential was only 3.933 mrem in 2014 (Section 6.0, Table 1), with an average of 2.383 mrem per year in 2005-2014. The dose to the general public that did not consume wild game was 0.213 mrem in 2014. The median, 1.448 mrem, is viewed as the best representation of the central tendency over the period 2005-2014, and is still a protective estimate (see Dose Critique Section).

The MEI scenario includes all potential dose as a worst-case dose exposure. The SCDHEC MEI survivalist was a sportsman and a wild plant and mushroom consumer who received a maximum dose of 11.995 mrem in 2014 (Section 4.0, Table 1). The SCDHEC MEI dose estimate represents an upper bound of all SCDHEC detected dose potential and is not potentially achievable unless all dose maximums could somehow be stored and maintained as a constant exposure throughout the year. Only one individual could receive this dose, since most of the dose required that individual to consume all of the edible portion from the specific animals used as the dose basis.

The AEI dose (3.933 mrem in 2014; Section 4.0, Table 1) basis should apply to the rest of the

population on an average potential basis and still be protective because it is based on detections only. Since even the AEI dose basis was protective and inflated, the median dose may better represent the typical individual who did not consume the animals containing the maximum dose. This AEI dose for the period 2005-2014 averaged 2.239 mrem per year (Section 6.0, Table 2), with a total median dose of 1.448 mrem per year.

Additional dose added primarily from DOE-SR onsite estimates for sportsmen increased the combined onsite and offsite dose potential to 37.2 mrem for the combined MEI. This improbable combined MEI potential accumulated dose was less than the DOE-SR 100 mrem annual dose release standard to the public in 2014 (Section 4.0, Table 3). Most of the dose in the DOE-SR and SCDHEC estimates was due to Cs-137 in wild game.

The SCDHEC 2014 MEI dose estimates relative to the DOE standard atmospheric (0.003 mrem from air inhalation) and liquid (0.619 mrem from drinking water ingestion; Section 4.0, Table 1) pathways, excluding the atypical dose pathways, were less than the respective 10 mrem and 4 mrem DOE Order 5400.5 (USDOE 1993) limits despite dose additions from other years inherent in field collected media. The DOE limits apply only to yearly DOE releases and not to dose accumulated in the environment and are not applicable to SCDHEC field detections. The all-pathway DOE atmospheric and liquid estimates for the general public exclude atypical dose (game e.g.), which was captured under the total MEI estimate for comparison to the DOE defined dose limit for all annual dose releases to the public (100 mrem/yr; SRNS 2015).

The SCDHEC critical pathway estimates included atypical dose that was primarily due to Cs-137 exposure from ingested game animals (deer and hog). Inhalation was 0.05 percent of the AEI dose to the critical pathway, food ingestion was 98.75 percent, water ingestion was 1.17 percent, and direct exposure was 0.03 percent in 2014 (numbers derived from Section 4.0, Table 1). The primary critical pathways for dose exposure were via atmospheric and liquid dose that was eventually ingested directly from food sources. The 2005-2014 statistics reduce sampling selection variations and gives a more accurate characterization of the central tendency potential in critical pathway dose (22.394 mrem of dose over a 10 year period; Section 6.0, Table 1).

The dose accumulations in the major critical pathways were atmospheric (72.44 percent or 16.223 mrem), and liquid (27.56 percent or 6.171 mrem; Section 6.0, Table 1). The observed potential dose for this 10 year period (22.394 mrem) can be broken down into the following subpathways: food ingestion (94.60 percent or 21.185 mrem), drinking water (5.01 percent or 1.122 mrem), direct exposure (0.29 percent or 0.064 mrem), and inhalation (0.10 percent or 0.023 mrem). These exposures were well below all applicable limits.

The 2014 primary AEI radionuclide dose contributors were Cs-137 (97.66 percent) followed by contributions from tritium (2.31 percent), and strontium (0.03 percent) on an AEI basis. For the MEI, the primary contributors to dose were Cs-137 (91.22 percent), followed by tritium (8.76 percent), and strontium (0.02 percent). Cs-137 was the primary contributor to accumulated AEI dose in the 2005-2014 timeframe, primarily through the consumption of wild game.

These findings indicated that monitoring of bioaccumulation of radionuclides and the resulting dose should continue in addition to the primary inhalation, ingestion, and direct exposure routes from the typical atmospheric and liquid pathways. The down-gradient wells, surface water,

sediments, plants, and animals should be carefully monitored for any signs of the contaminants that are present at basins, seepage areas, and the F and H-Area tank farms. Early detection is paramount to protecting the public and the environment if a release to offsite streams or groundwater occurs. SCDHEC will continue to monitor SRS and adjacent area for the primary radionuclide contributors to dose potentially associated with DOE-SR operations.

	SCDHEC plus DOE-SR MEI Additions <sup>9,10</sup>	NA	37.2	NA

Notes:

- 1 - DOE-SR data primarily from Table 6-5 (SRNS 2015).
- 2 - SCDHEC maximums or single highest detection basis for all media per route of exposure (Table 1).
- 3 - MEI all-source 2014 dose additions. Some DOE-SR dose is based on computer modeling.
- 4 - Sum of SCDHEC fish, wading exposure, swimming ingestion, Savannah River derived drinking water, vegetation, and milk (all MEI).
- 5 - DOE-SR fish dose is the sum of the creek-mouth fisherman and the total offsite fisherman doses. SCDHEC fish dose includes fisherman soil exposure dose.
- 6 - Soil sources were from Creek Plantation (DOE-SR) and direct exposure from farm soil (SCDHEC).
- 7 - Edible fungi was not sampled in 2014.
- 8 - This comes from the Section 4.0 Table 1 MEI Column-It is not a summation of the SCDHEC column.
- 9 - Biased high primarily due to single maximums (SCDHEC) and DOE-SR dose based on releases. Not all released dose is absorbed, and explains why field measurements do not detect all dose released.
- 10 - The SCDHEC Added Dose Basis serves as a quantification of combined offsite and onsite dose that is available in the environment to a hypothetical individual-the MEI. It should not be construed as a measurement of dose that any one individual is likely to receive.

Figure 3. AEI Cumulative Food Dose: 2005-2014

Note: This graph shows the total food AEI dose trend and the trend for the primary contributor to the dose.

Figure 4. AEI Cumulative Water Dose: 2005-2014

Notes:

1. This graph shows the total water AEI dose trend and the trend for the primary contributor to the dose.
2. Public water system drinking water from the Savannah River was not sampled in 2010.

Figure 5. AEI Cumulative Dose from Minor Sources: 2005-2014

Note: This graph shows the total minor sources AEI dose trend and the trend for the primary contributor to the dose.

Notes:

1. Sr-89/90 was removed from SCDHEC dose calculations as it is primarily found in a part of the fish (bone tissue) that is not usually eaten.
2. CR refers to consumption rate.

**2014 AEI Milk Dose**

Potential Dose from Milk (AEI)					Total Dose	mrem
Media	Radionuclide	Activity	CR	Dose		
		pCi/L	kg/yr	mrem		
Milk	H-3	370	69.0	0.002		
	Sr-89/90	0.627	69.0	0.001		
	I-131	There were no detections in 2014.				
Milk Dose Average				0.001	All Milk Sum	0.002

**2014 MEI Milk Dose**

Potential Dose from Milk (MEI)					Total Dose	mrem
Media	Radionuclide	Activity	CR	Dose		
		pCi/L	kg/yr	mrem		
Milk	H-3	370	260.0	0.006		
	Sr-89/90	0.774	260.0	0.002		
	I-131	There were no detections in 2014.				
Milk Dose Average				0.004	All Milk Sum	0.009

**2014 AEI Wild Game Dose**

Avg. Potential Dose From Game (AEI)			Total Dose	mrem
Media	Radionuclide	Dose (mrem)		
Avg. Deer	Cs-137	1.28		
Avg. Hog	Cs-137	2.44		
Game Dose Average		1.86	Game Sum	3.72

**2014 MEI Wild Game Dose**

Avg. Potential Dose From Game (MEI)			Total Dose	mrem
Media	Radionuclide	Dose (mrem)		
Avg. Deer	Cs-137	5.31		
Avg. Hog	Cs-137	4.43		
Game Dose Average		4.87	Game Sum	9.74

**2014 AEI Edible Vegetation Dose**

Potential Dose in Edible Vegetation (AEI)					Total Dose	mrem
Media	Radionuclide	Activity	CR	Dose		
		pCi/g	kg/yr	mrem		
All Leafy	H-3	There were no detections in 2014.				
	Cs-137	There were no detections in 2014.				
	Sr-89/90	There were no detections in 2014.				
All Leafy Vegetables Average				NA	Leafy Vegetables	0.000
All Fruit	H-3	7.212	89	0.041		
	Cs-137	There were no detections in 2014.				
	Sr-89/90	There were no detections in 2014.				
Fruit nonNORM Average				0.041	Fruit	0.041
Fungi	H-3	NA	NA	NA	Fungi was not collected in 2014.	
	Cs-137	NA	NA	NA		
	SR-89/90	NA	NA	NA		
	Pu-238	NA	NA	NA		
	Pu-239/40	NA	NA	NA		
Fungi Average				NA	Fungi	NA
Combined Vegetation Average				0.041	Vegetation Sum	0.041

**2014 MEI EdibleVegetation Dose**

Potential Dose in Edible Vegetation (MEI)					Total Dose	mrem
Media	Radionuclide	Activity	CR	Dose		
		pCi/g	kg/yr	mrem		
All Leafy	H-3	There were no detections in 2014.				
	Cs-137	There were no detections in 2014.				
	SR-89/90	There were no detections in 2014.				
All Leafy Vegetables Average				NA	Leafy Vegetables	0.000
All Fruit	H-3	22.618	289	0.419		
	Cs-137	There were no detections in 2014.				
	Sr-89/90	There were no detections in 2014.				
Fruit nonNORM Average				0.419	Fruit	0.419
Fungi	H-3	NA	NA	NA	Fungi was not collected in 2014.	
	Cs-137	NA	NA	NA		
	SR-89/90	NA	NA	NA		
	Pu-238	NA	NA	NA		
	Pu-239/40	NA	NA	NA		
Fungi Average				NA	Fungi	0.000
Combined Vegetation Average				0.419	Vegetation Sum	0.419

**2014 AEI Ingestion from Surface Water and Wells Dose**

Ingestion from Surface Water and Wells (AEI)					Total Dose	mrem
Source	Radionuclide	Activity	CR	Dose		
Savannah River Sourced Drinking Water		pCi/L	L/yr	mrem		
SW	H-3	429	300	0.008	SRSDW	0.008
Groundwater Sourced Drinking Water		pCi/L	L/yr	mrem		
GW	H-3	<LLD	300	0.000		
DNR and Private Wells Groundwater		pCi/L	L/yr	mrem		
GW	H-3	251	300	0.005	GSDW	0.005
Nonpotable Drinking Water		pCi/L	L/yr	mrem		
SW	H-3	965	300	0.019	NPDW	0.019
Rainwater	H-3	293	300	0.006	NPDW	0.006
Nonpotable Average Dose Potential from All Sources				0.012	Total	0.037

Note: Nonpotable drinking water is surface water or collected rainwater that has been treated in small batches by an individual through boiling or the addition of iodine.

**2014 MEI Ingestion from Surface Water and Wells Dose**

Ingestion from Surface Water and Wells (MEI)					Total Dose	mrem
Source	Radionuclide	Activity	CR	Dose		
Savannah River Sourced Drinking Water		pCi/L	L/yr	mrem		
SW	H-3	945	800	0.048	SRSDW	0.048
Groundwater Sourced Drinking Water		pCi/L	L/yr	mrem		
GW	H-3	<LLD	800	0.000		
DNR and Private Wells Groundwater		pCi/L	L/yr	mrem		
GW	H-3	251	800	0.013	GSDW	0.013
Nonpotable Drinking Water		pCi/L	L/yr	mrem		
SW	H-3	5877	800	0.301	NPDW	0.301
Rainwater	H-3	452	800	0.023	NPDW	0.023
Nonpotable Average Dose Potential from All Sources				0.162	Total	0.386

Note: Nonpotable drinking water is surface water or collected rainwater that has been treated in small batches by an individual through boiling or the addition of iodine.

**2014 AEI Accidental Water Ingestion and Direct Exposure from Water Dose**

Streams and Savannah River Surface Water Samples (AEI)					Total Dose	mrem
Source	Radionuclide	Activity	CR	Dose		
Surface Water Swimming		pCi/L	hrs/yr	mrem		
Ingestion	H-3	2416	540	0.008	Surface Water Swimming	0.008
Incidental ingestion of water while swimming at Savannah River Site Creek Mouths						
Surface Water Immersion		pCi/L	hrs/yr	mrem		
Immersion	H-3	2416	540	0.000	Surface Water Immersion	0.000
Direct exposure to the skin while swimming at SRS Creek Mouths.						
Streams and Savannah River Surface Water Samples (AEI) Total						0.008

**2014 MEI Accidental Water Ingestion and Direct Exposure from Water Dose**

Streams and Savannah River Surface Water Samples (MEI)					Total Dose	mrem
Source	Radionuclide	Activity	CR	Dose		
Surface Water Swimming		pCi/L	hrs/yr	mrem		
Ingestion	H-3	16797	2172	0.234	Surface Water Swimming	0.234
Incidental ingestion of water while swimming at Savannah River Site Creek Mouths						
Surface Water Immersion		pCi/L	hrs/yr	mrem		
Immersion	H-3	16797	2172	0.000	Surface Water Immersion	0.000
Direct exposure to the skin while swimming at SRS Creek Mouths.						
Streams and Savannah River Surface Water Samples (MEI) Total						0.234

**2014 AEI Sediment at Creek Mouths and Boat Landings Dose**

Sediment at Creek Mouths and Boat Landings					Total Dose	mrem
Source	Radionuclide	Activity	CR	Dose		
Sediment Dose		pCi/g	hrs/yr	mrem		
Creek Mouths	Cs-137	0.890	540	0.001		
	Pu-238	0.015	540	0.000		
	Pu-239/240	0.004	540	0.000	Creek Mouths	0.001
Boat Landings	Cs-137	0.350	540	0.000	Boat Landings	0.000
Average Dose from Sediment				0.000	Overall	0.001

**2014 MEI Sediment at Creek Mouths and Boat Landings Dose**

Sediment at Creek Mouths and Boat Landings					Total Dose	mrem
Source	Radionuclide	Activity	CR	Dose		
Sediment Dose		pCi/g	hrs/yr	mrem		
Creek Mouths	Cs-137	2.3	2172	0.007		
	Pu-238	0.32	2172	0.000		
	Pu-239/240	0.006	2172	0.000	Creek Mouths	0.007
Boat Landings	Cs-137	1.94	2172	0.006	Boat Landings	0.006
Average Dose from Sediment				0.003	Overall	0.013

**2014 AEI Surface Soil Ingestion Dose**

Surface Soil Ingestion (AEI)				Total Dose	mrem	
Surface Soil (SS)	Activity (pCi/g)	CR (mg/day)	Dose (mrem)			
Ingestion	Cs-137	0.10	20			0.000
Soil Ingestion Average Dose			0.000			
Total Surface Soil Ingestion (AEI)					0.000	

Note: This represents soil inadvertently consumed with plants.

**2014 MEI Surface Soil Ingestion Dose**

Surface Soil Ingestion (MEI)				Total Dose	mrem	
Surface Soil (SS)	Activity (pCi/g)	CR (mg/day)	Dose (mrem)			
Ingestion	Cs-137	0.18	20			0.000
Soil Ingestion Average Dose			0.000			
Total Surface Soil Ingestion (MEI)					0.000	

Note: This represents soil inadvertently consumed with plants.

**2014 AEI Soil Shine Dose**

Soil Shine (AEI)				Total Dose	mrem	
Surface Soil	Activity (pCi/g)	CR (hrs/yr)	Dose (mrem)			
Shine	Cs-137	0.10	2602			0.000
Shine or Direct Exposure from Farm Soil Average			0.000			
Total Surface Soil Shine (AEI)					0.000	

**2014 MEI Soil Shine Dose**

Soil Shine (MEI)				Total Dose	mrem	
Surface Soil	Activity (pCi/g)	CR (hrs/yr)	Dose (mrem)			
Shine	Cs-137	0.18	2602			0.001
Shine or Direct Exposure from Farm Soil Average			0.001			
Total Surface Soil Shine (MEI)					0.001	

**2014 AEI Atmospheric Inhalation Dose**

Atmospheric Inhalation (AEI)					Total Dose	mrem
Surface Soil Resuspension and Air Inhalation						
Surface Soil Resuspension	Activity (pCi/g)	CR (m3/yr)	Dose (mrem)			
Inhalation	Cs-137	0.10	5000	0.000	Surface Soil Resuspension	0.000
Air Inhalation (Silica Gel)	Activity (pCi/m <sup>3</sup> )	CR (m3/yr)	Dose (mrem)			
Inhalation	H-3	4.92	5000	0.002	Air Inhalation	0.002
Atmospheric Inhalation Average Dose				0.001	Total Atmospheric Inhalation	0.002

**2014 MEI Atmospheric Inhalation Dose**

Atmospheric Inhalation (MEI)					Total Dose	mrem
Surface Soil Resuspension and Air Inhalation						
Surface Soil Resuspension	Activity (pCi/g)	CR (m3/yr)	Dose (mrem)			
Inhalation	Cs-137	0.18	6400	0.000	Surface Soil Resuspension	0.000
Air Inhalation (Silica Gel)	Activity (pCi/m <sup>3</sup> )	CR (m3/yr)	Dose (mrem)			
Inhalation	H-3	7.53	6400	0.003	Air Inhalation	0.003
Atmospheric Inhalation Average Dose				0.002	Total Atmospheric Inhalation	0.003

13.6.0 Summary Statistics

2014 Critical Pathway Dose Report

Table 1. 2005-2014 AEI Exposure per Media: Total AEI Dose and Percentage

Pathway	AEI Media Categories	2014 <sup>1</sup>	2005-2014 <sup>2</sup>	2005-2014 AEI % Basis <sup>3</sup>	Number of Years <sup>4</sup>
Atmospheric	Surface Soil Resuspension Inhalation	0.000	0.000	0.00	6
Atmospheric	H-3 Inhalation	0.002	0.023	0.10	10
Liquid	Fish	0.121	5.148	22.99	10
Atmospheric	Cow Milk	0.002	0.224	1.00	10
Atmospheric	Wild Game	3.720	12.569	56.13	10
Atmospheric	Vegetation (Leafy and Fruit)	0.041	1.132	5.05	10
Atmospheric	Fungi (Not Sampled in 2014)	NS	2.112	9.43	6
Atmospheric	Soil Ingestion with Food	0.000	0.000	0.00	6
Liquid	Public System Drinking Water From the Sav. River	0.008	0.224	1.00	9
Liquid	Public System Drinking Water from Groundwater	0.000	0.114	0.51	10
Liquid	DNR and Private Wells	0.005	0.195	0.87	10
Liquid	Nonpotable Drinking Water (Savannah River)	0.019	0.407	1.82	10
Atmospheric	Nonpotable Drinking Water (Rainwater)	0.006	0.124	0.55	10
Liquid	Ingestion from Swimming	0.008	0.058	0.26	10
Liquid	Direct Exposure from Swimming	0.000	0.000	0.00	4
Liquid	Direct Exposure from Wading	0.001	0.025	0.11	10
Atmospheric	Direct Exposure from Farm Soil	0.000	0.039	0.17	10
Totals		3.933	22.394	100	NA

Notes:

1. The 2014 column is dose in mrem during 2014.
2. The 2005-2014 column is total dose in mrem over the 2005-2014 ten year period.
3. The AEI % basis column is the percentage of 2005-2014 dose due to a given media.
4. Number of years refers to the number of years data was available for 2005-2014.

Table 2. 2005-2014 AEI Exposure per Media: Average and Median Yearly Dose

Pathway	AEI Media Categories	Avg. Yearly Dose <sup>1</sup>	SD	Median Yearly Dose <sup>2</sup>
Atmospheric	Surface Soil Resuspension Inhalation	0.000	0.000	0.000
Atmospheric	H-3 Inhalation	0.002	0.003	0.002
Liquid	Fish	0.515	0.279	0.492
Atmospheric	Cow Milk	0.022	0.063	0.003
Atmospheric	Wild Game	1.257	1.495	0.566
Atmospheric	Vegetation (Leafy and Fruit)	0.113	0.130	0.083
Atmospheric	Fungi	0.352	0.354	0.220
Atmospheric	Soil Ingestion with Food	0.000	0.000	0.000
Liquid	Public System Drinking Water From the Sav. River	0.025	0.023	0.018
Liquid	Public System Drinking Water from Groundwater	0.011	0.016	0.005
Liquid	DNR and Private Wells	0.020	0.046	0.005
Liquid	Nonpotable Drinking Water (Savannah River)	0.041	0.031	0.032
Atmospheric	Nonpotable Drinking Water (Rainwater)	0.012	0.006	0.014
Liquid	Ingestion from Swimming	0.006	0.007	0.005
Liquid	Direct Exposure from Swimming	0.000	0.000	0.000
Liquid	Direct Exposure from Wading	0.003	0.003	0.002
Atmospheric	Direct Exposure from Farm Soil	0.004	0.007	0.001
Totals		2.383	NA	1.448

Notes:

1. Average yearly dose is the yearly AEI average in mrem for the 2005-2014 time period.
2. Median yearly dose is median AEI dose in mrem for the 2005-2014 time period.
